# Rendering pathways to convey quantitative genomic relationships

# VJ Carey et al

#### April 21, 2009

# 1 Introduction

Given an R graph representing a biological pathway and a vector of numbers (e.g., estimated levels of gene expression, or quantile of gene expression value in a distribution over samples) linked to the nodes of the pathway (e.g., genes), we wish to display the graph with nodes colored to convey the relationships among the numbers.

Our primary tool for rendering graphs is *Rgraphviz*. This package uses AT&T graphviz to compute layouts, and various aspects of R graphics to create renderings.

Our primary tools for creating pathway graphs are the *graph* and *pathRender* packages.

In this vignette and associated code, we aim to simplify the use of software in these components to allow the intended renderings to be created in a flexible way.

# 2 An example

#### 2.1 A pathway graph

The graph package contains a custom-made graph representing the pancreatic cancer initiation pathway. First we render it in isolation from data:

```
> library(graph)
> library(Rgraphviz)
> data(pancrCaIni)
> plot(pancrCaIni, nodeAttrs = pwayRendAttrs(pancrCaIni))
```

Note that the default rendering of the pathway graph is hard to read; we use the new pwayRendAttrs function to generate attributes that improve readability.

# 2.2 An ExpressionSet and its reduction

We will work with ALL.

# > library(ALL) > if (!exists("ALL")) data(ALL)

A basic problem is to reduce the information obtained using the whole-genome microarray to a set of numbers relevant to the pathway we wish to render. The reduceES function helps with this. Given a vector of annotation tokens (e.g., HUGO gene symbols) and a map from symbols to associated microarray probes, reduceES restricts the assay data to relevant probes. The map parameter can be either an AtomicAnnDbBimap as created in the \*.db annotation packages, or a list with annotation tokens as element names and vectors probe identifiers as elements. Here we illustrate the use of the Bimap:

```
> if ("package:hgu95av2" %in% search()) detach("package:hgu95av2")
> library(hgu95av2.db)
> red1 = reduceES(ALL, nodes(pancrCaIni), revmap(hgu95av2SYMBOL),
+
      "symbol")
> red1
ExpressionSet (storageMode: lockedEnvironment)
assayData: 28 features, 128 samples
  element names: exprs
phenoData
  sampleNames: 01005, 01010, ..., LAL4 (128 total)

Note that the reduceES creates a featureData variable and that there are repetitions of values of this variable. We can specify that we want to collapse repetitions by specifying a function for the collapseFun parameter. We will use mean.

```
> collap1 = reduceES(ALL, nodes(pancrCaIni), revmap(hgu95av2SYMBOL),
      "symbol", mean)
+
> collap1
ExpressionSet (storageMode: lockedEnvironment)
assayData: 18 features, 128 samples
  element names: exprs
phenoData
  sampleNames: 01005, 01010, ..., LAL4 (128 total)
  varLabels and varMetadata description:
    cod: Patient ID
    diagnosis: Date of diagnosis
    ...: ...
    date last seen: date patient was last seen
    (21 total)

  featureNames: AKT3, ARAF, ..., RALGDS (18 total)
 fvarLabels and fvarMetadata description:
    symbol: NA
experimentData: use 'experimentData(object)'
Annotation:
```

# 2.3 A rendering

Now we will render information on one sample from the reduced data.

- > library(RColorBrewer)
- > plotExGraph(pancrCaIni, collap1, 1)
