Package 'PECA'

October 9, 2015

Type Package

Title Probe-level Expression Change Averaging

Version 1.4.0

Author Tomi Suomi, Jukka Hiissa, Laura L. Elo

Maintainer Tomi Suomi <tomi.suomi@utu.fi>

Imports limma, affy, genefilter, preprocessCore

Suggests SpikeIn, ROCR, multtest

Description Calculates Probe-level Expression Change Averages (PECA) to identify differential expression in Affymetrix gene expression microarray studies or in proteomic studies using peptide-level mesurements respectively.

PECA

PECA differential gene expression

Description

Calculates the PECA ordinary or modified t-statistic to determine differential expression between two groups of samples in Affymetrix gene expression studies or peptide-based proteomic studies.

Usage

```
## Read AffyBatch object
PECA_AffyBatch(affy=NULL, normalize=FALSE, test="t", type="median", paired=FALSE)
## Read CEL-files
```

PECA_CEL(samplenames1=NULL, samplenames2=NULL, normalize=FALSE, test="t", type="median", paired=FALS

```
## Read tab separated text file
PECA_tsv(file=NULL, samplenames1=NULL, samplenames2=NULL, normalize=FALSE, test="t", type="median",
```

Read dataframe
PECA_df(df=NULL, id=NULL, samplenames1=NULL, samplenames2=NULL, normalize=FALSE, test="t", type="media"

Arguments

affy	AffyBatch object
normalize	a character string indicating if ("quantile") or ("median") normalization is per- formed
test	a character string indicating whether the ordinary ("t") or modified ("modt") t-test is performed
type	a character string indicating whether ("median") or ("tukey") is used when cal- culating gene/protein values
paired	a logical indicating whether a paired test is performed
file	filename of tab separated data
samplenames1	a character vector containing the names of the .CEL-files/columns in the first group
samplenames2	a character vector containing the names of the .CEL-files/columns in the second group
df	dataframe to be used as an input
id	column name of dataframe used for aggregating results

Details

PECA determines differential gene expression using directly the probe-level measurements from Affymetrix gene expression microarrays or proteomic datasets. An expression change between two groups of samples is first calculated for each probe/peptide on the array. The gene/protein-level expression changes are then defined as medians over the probe-level changes. For more details about the probe-level expression change averaging (PECA) procedure, see Elo et al. (2005), Laajala et al. (2009) and Suomi et al.

PECA calculates the probe-level expression changes using the ordinary or modified t-statistic. The ordinary t-statistic is calculated using the function rowttests in the Bioconductor genefilter package. The modified t-statistic is calculated using the linear modeling approach in the Bioconductor limma package. Both paired and unpaired tests are supported.

The significance of an expression change is determined based on the analytical p-value of the genelevel test statistic. Unadjusted p-values are reported along with the corresponding p-values looked

2

PECA

up from beta ditribution. The quality control and filtering of the data (e.g. based on low intensity or probe specificity) is left to the user.

Examples

```
## Load spike-in example
library(SpikeIn)
data(SpikeIn95)
## Subset the data
data <- SpikeIn95[,13:20]
## Run the test
results <- PECA_AffyBatch(affy=data)
## Show portion of the results
head(results)
```
