1 Introduction

1.1 Purpose of this document

This document is a collection of HOWTOs. Each HOWTO is a short section that demonstrates how to use the containers and operations implemented in the *GenomicRanges* and related packages (*IRanges*, *Biostrings*, *Rsamtools*, *GenomicAlign-*

ments, *Bsgenome*, and *GenomicFeatures*) to perform a task typically found in the context of a high throughput sequence analysis.

Unless stated otherwise, the *HOWTOs* are self contained, independent of each other, and can be studied and reproduced in any order.

1.2 Prerequisites and additional recommended reading

We assume the reader has some previous experience with *R* and with basic manipulation of *GRanges*, *GRangesList*, *Rle*, *RleList*, and *DataFrame* objects. See the “An Introduction to Genomic Ranges Classes” vignette located in the *GenomicRanges* package (in the same folder as this document) for an introduction to these containers.

Additional recommended readings after this document are the “Software for Computing and Annotating Genomic Ranges” paper [Lawrence et al. (2013)] and the “Counting reads with *summarizeOverlaps*” vignette located in the *GenomicAlignments* package.

To display the list of vignettes available in the *GenomicRanges* package, use `browseVignettes("GenomicRanges")`.

1.3 Input data and terminology used across the HOWTOs

In order to avoid repetition, input data, concepts and terms used in more than one *HOWTO* are described here:

- **The *pasillaBamSubset* data package:** contains both a BAM file with single-end reads (`untreated1_chr4`) and a BAM file with paired-end reads (`untreated3_chr4`). Each file is a subset of chr4 from the “Pasilla” experiment.

```
> library(pasillaBamSubset)
> untreated1_chr4()
[1] "/home/biocbuild/bbs-3.1-bioc/R/library/pasillaBamSubset/extdata/untreated1_chr4.bam"
> untreated3_chr4()
[1] "/home/biocbuild/bbs-3.1-bioc/R/library/pasillaBamSubset/extdata/untreated3_chr4.bam"
See ?pasillaBamSubset for more information.
> ?pasillaBamSubset
```
- **Gene models and *TxDb* objects:** A *gene model* is essentially a set of annotations that describes the genomic locations of the known genes, transcripts, exons, and CDS, for a given organism. In *Bioconductor* it is typically represented as a *TxDb* object but also sometimes as a *GRanges* or *GRangesList* object. The *GenomicFeatures* package contains tools for making and manipulating *TxDb* objects.

2 HOWTOs

2.1 How to read single-end reads from a BAM file

As sample data we use the *pasillaBamSubset* data package described in the introduction.

```
> library(pasillaBamSubset)
> un1 <- untreated1_chr4() # single-end reads
```

Several functions are available for reading BAM files into *R*:

```
readGAlignments()
readGAlignmentPairs()
readGAlignmentsList()
scanBam()
```

`scanBam` is a low-level function that returns a list of lists and is not discussed further here. See `?scanBam` in the *Rsamtools* package for more information.

Single-end reads can be loaded with the `readGAlignments` function from the [GenomicAlignments](#) package.

```
> library(GenomicAlignments)
> gal <- readGAlignments(un1)
```

Data subsets can be specified by genomic position, field names, or flag criteria in the `ScanBamParam`. Here we input records that overlap position 1 to 5000 on the negative strand with `flag` and `cigar` as metadata columns.

```
> what <- c("flag", "cigar")
> which <- GRanges("chr4", IRanges(1, 5000))
> flag <- scanBamFlag(isMinusStrand = TRUE)
> param <- ScanBamParam(which=which, what=what, flag=flag)
> neg <- readGAlignments(un1, param=param)
> neg
```

GAlignments object with 37 alignments and 2 metadata columns:

	seqnames	strand	cigar	qwidth	start	end
	<Rle>	<Rle>	<character>	<integer>	<integer>	<integer>
[1]	chr4	-	75M	75	892	966
[2]	chr4	-	75M	75	919	993
[3]	chr4	-	75M	75	967	1041
...
[35]	chr4	-	75M	75	4997	5071
[36]	chr4	-	75M	75	4998	5072
[37]	chr4	-	75M	75	4999	5073
	width	njunc		flag	cigar	
	<integer>	<integer>		<integer>	<character>	
[1]	75	0		16	75M	
[2]	75	0		16	75M	
[3]	75	0		16	75M	
...	
[35]	75	0		16	75M	
[36]	75	0		16	75M	
[37]	75	0		16	75M	

seqinfo: 8 sequences from an unspecified genome

Another approach to subsetting the data is to use `filterBam`. This function creates a new BAM file of records passing user-defined criteria. See `?filterBam` in the [Rsamtools](#) package for more information.

2.2 How to read paired-end reads from a BAM file

As sample data we use the [pasillaBamSubset](#) data package described in the introduction.

```
> library(pasillaBamSubset)
> un3 <- untreated3_chr4() # paired-end reads
```

Paired-end reads can be loaded with the `readGAlignmentPairs` or `readGAlignmentsList` function from the [GenomicAlignments](#) package. These functions use the same mate paring algorithm but output different objects.

Let's start with `readGAlignmentPairs`:

```
> un3 <- untreated3_chr4()
> gapairs <- readGAlignmentPairs(un3)
```

The `GAlignmentPairs` class holds only pairs; reads with no mate or with ambiguous pairing are discarded. Each list element holds exactly 2 records (a mated pair). Records can be accessed as the first and last segments in a template or as left and right alignments. See `?GAlignmentPairs` in the [GenomicAlignments](#) package for more information.

```
> gapairs
```

```
GAlignmentPairs object with 75346 alignment pairs and 0 metadata columns:
  seqnames strand   :           ranges   --           ranges
    <Rle>  <Rle>   :           <IRanges> --           <IRanges>
[1]     chr4      +   : [169, 205] --           [ 326, 362]
[2]     chr4      +   : [943, 979] --           [1086, 1122]
[3]     chr4      +   : [944, 980] --           [1119, 1155]
...
[75344]   chr4      +   : [1348217, 1348253] -- [1348215, 1348251]
[75345]   chr4      +   : [1349196, 1349232] -- [1349326, 1349362]
[75346]   chr4      +   : [1349708, 1349744] -- [1349838, 1349874]
-----
seqinfo: 8 sequences from an unspecified genome
```

For `readGAlignmentsList`, mate pairing is performed when `asMates` is set to `TRUE` on the `BamFile` object, otherwise records are treated as single-end.

```
> galist <- readGAlignmentsList(BamFile(un3, asMates=TRUE))
```

`GAlignmentsList` is a more general ‘list-like’ structure that holds mate pairs as well as non-mates (i.e., singletons, records with unmapped mates etc.) A `mates_status` metadata column (accessed with `mcols`) indicates which records were paired.

```
> galist
```

```
GAlignmentsList object of length 96636:
```

```
[[1]]
```

```
GAlignments object with 2 alignments and 0 metadata columns:
```

	seqnames	strand	cigar	qwidth	start	end	width	njunc
[1]	chr4	+	37M	37	169	205	37	0
[2]	chr4	-	37M	37	326	362	37	0

```
[[2]]
```

```
GAlignments object with 2 alignments and 0 metadata columns:
```

	seqnames	strand	cigar	qwidth	start	end	width	njunc
[1]	chr4	+	37M	37	946	982	37	0
[2]	chr4	-	37M	37	986	1022	37	0

```
[[3]]
```

```
GAlignments object with 2 alignments and 0 metadata columns:
```

	seqnames	strand	cigar	qwidth	start	end	width	njunc
[1]	chr4	+	37M	37	943	979	37	0
[2]	chr4	-	37M	37	1086	1122	37	0

```
...
```

```
<96633 more elements>
```

```
-----
```

```
seqinfo: 8 sequences from an unspecified genome
```

Non-mated reads are returned as groups by QNAME and contain any number of records. Here the non-mate groups range in size from 1 to 9.

```
> non_mates <- galist[mcols(galist)$mate_status == "unmated"]
> table(elementLengths(non_mates))
```

1	2	3	4	5	6	7	8	9
18191	2888	69	60	7	8	2	1	1

2.3 How to read and process a big BAM file by chunks in order to reduce memory usage

A large BAM file can be iterated through in chunks by setting a `yieldSize` on the `BamFile` object. As sample data we use the `pasillaBamSubset` data package described in the introduction.

```
> library(pasillaBamSubset)
> un1 <- untreated1_chr4()
> bf <- BamFile(un1, yieldSize=100000)
```

Iteration through a BAM file requires that the file be opened, repeatedly queried inside a loop, then closed. Repeated calls to `readGAlignments` without opening the file first result in the same 100000 records returned each time.

```
> open(bf)
> cvg <- NULL
> repeat {
+   chunk <- readGAlignments(bf)
+   if (length(chunk) == 0L)
+     break
+   chunk_cvg <- coverage(chunk)
+   if (is.null(cvg)) {
+     cvg <- chunk_cvg
+   } else {
+     cvg <- cvg + chunk_cvg
+   }
+ }
> close(bf)
> cvg

...
<3 more elements>
```

2.4 How to compute read coverage

The “read coverage” is the number of reads that cover a given genomic position. Computing the read coverage generally consists in computing the coverage at each position in the genome. This can be done with the `coverage()` function.

As sample data we use the `pasillaBamSubset` data package described in the introduction.

```
> library(pasillaBamSubset)
> un1 <- untreated1_chr4() # single-end reads
> library(GenomicAlignments)
> reads1 <- readGAlignments(un1)
> cvg1 <- coverage(reads1)
> cvg1

RleList of length 8

  Values :    0     1     2     3     4     5 ...    0     1     0     1     0

...
<3 more elements>

Coverage on chr4:

> cvg1$chr4

integer-Rle of length 1351857 with 122061 runs
  Lengths:  891   27     5   12   13   45 ... 106   75 1600   75 1659
  Values :    0     1     2     3     4     5 ...    0     1     0     1     0

Average and max coverage:

> mean(cvg1$chr4)
[1] 11.33746
> max(cvg1$chr4)
[1] 5627
```

Note that `coverage()` is a generic function with methods for different types of objects. See `?coverage` for more information.

2.5 How to find peaks in read coverage

ChIP-Seq analysis usually involves finding peaks in read coverage. This process is sometimes called “peak calling” or “peak detection”. Here we’re only showing a naive way to find peaks in the object returned by the `coverage()` function. *Bioconductor* packages `BayesPeak`, `bumphunter`, `Starr`, `CexoR`, `exomePeak`, `RIPSeeker`, and others, provide sophisticated peak calling tools for ChIP-Seq, RIP-Seq, and other kind of high throughput sequencing data.

Let’s assume `cvg1` is the object returned by `coverage()` (see previous *HOWTO* for how to compute it). We can use the `slice()` function to find the genomic regions where the coverage is greater or equal to a given threshold.

```
> chr4_peaks <- slice(cvg1$chr4, lower=500)
> chr4_peaks
```

Views on a 1351857-length Rle subject

2.6 How to retrieve a gene model from the UCSC genome browser

See introduction for a quick description of what *gene models* and *TxDb* objects are. We can use the `makeTranscriptDbFromUCSC()` function from the `GenomicFeatures` package to import a UCSC genome browser track as a *TxDb* object.

```
> library(GenomicFeatures)
> ### Internet connection required! Can take several minutes...
> txdb <- makeTxDbFromUCSC(genome="sacCer2", tablename="ensGene")
```

See `?makeTxDbFromUCSC` in the `GenomicFeatures` package for more information.

Note that some of the most frequently used gene models are available as *TxDb* packages. A *TxDb* package consists of a pre-made *TxDb* object wrapped into an annotation data package. Go to http://bioconductor.org/packages/release/BiocViews.html#_TxDb to browse the list of available *TxDb* packages.

```
> library(TxDb.Hsapiens.UCSC.hg19.knownGene)
> txdb <- TxDb.Hsapiens.UCSC.hg19.knownGene
> txdb

TxDb object:
# Db type: TxDb
# Supporting package: GenomicFeatures
# Data source: UCSC
# Genome: hg19
# Organism: Homo sapiens
# UCSC Table: knownGene
# Resource URL: http://genome.ucsc.edu/
# Type of Gene ID: Entrez Gene ID
# Full dataset: yes
# miRBase build ID: GRCh37
# transcript_nrow: 82960
# exon_nrow: 289969
# cds_nrow: 237533
# Db created by: GenomicFeatures package from Bioconductor
# Creation time: 2015-03-19 13:55:51 -0700 (Thu, 19 Mar 2015)
# GenomicFeatures version at creation time: 1.19.32
# RSQLite version at creation time: 1.0.0
# DBSCHEMAVERSION: 1.1
```

Extract the transcript coordinates from this gene model:

```
> transcripts(txdb)

GRanges object with 82960 ranges and 2 metadata columns:
      seqnames      ranges strand |      tx_id

```

2.7 How to retrieve a gene model from Ensembl

See introduction for a quick description of what *gene models* and *TxDb* objects are. We can use the `makeTxDbFromBiomart()` function from the `GenomicFeatures` package to retrieve a gene model from the Ensembl Mart.

```

> library(GenomicFeatures)
> ### Internet connection required! Can take several minutes...
> txdb <- makeTxDbFromBiomart(biomart="ensembl",
+                                dataset="hsapiens_gene_ensembl")

```

See `?makeTxDbFromBiomart` in the `GenomicFeatures` package for more information.

Note that some of the most frequently used gene models are available as *TxDb* packages. A *TxDb* package consists of a pre-made *TxDb* object wrapped into an annotation data package. Go to http://bioconductor.org/packages/release/BiocViews.html#__TxDb to browse the list of available *TxDb* packages.

```

> library(TxDb.Athaliana.BioMart.plantsmart22)
> txdb <- TxDb.Athaliana.BioMart.plantsmart22
> txdb

TxDb object:
# Db type: TxDb
# Supporting package: GenomicFeatures
# Data source: BioMart
# Organism: Arabidopsis thaliana
# Resource URL: www.biomart.org:80
# BioMart database: plants_mart_22
# BioMart database version: ENSEMBL PLANTS 22 (EBI UK)
# BioMart dataset: athaliana_eg_gene
# BioMart dataset description: Arabidopsis thaliana genes (TAIR10 (2010-09-TAIR10))
# BioMart dataset version: TAIR10 (2010-09-TAIR10)
# Full dataset: yes
# miRBase build ID: NA
# transcript_nrow: 41671
# exon_nrow: 171013
# cds_nrow: 147494
# Db created by: GenomicFeatures package from Bioconductor
# Creation time: 2014-09-26 11:23:54 -0700 (Fri, 26 Sep 2014)
# GenomicFeatures version at creation time: 1.17.17
# RSQLite version at creation time: 0.11.4
# DBSCHEMAVERSION: 1.0

```

Extract the exon coordinates from this gene model:

```

> exons(txdb)

```

2.8 How to load a gene model from a GFF or GTF file

See introduction for a quick description of what *gene models* and *TxDb* objects are. We can use the `makeTxDbFromGFF()` function from the [GenomicFeatures](#) package to import a GFF or GTF file as a *TxDb* object.

```
> library(GenomicFeatures)
> gff_file <- system.file("extdata", "GFF3_files", "a.gff3",
+                           package="GenomicFeatures")
> txdb <- makeTxDbFromGFF(gff_file, format="gff3")
> txdb

TxDb object:
# Db type: TxDb
# Supporting package: GenomicFeatures
# Data source: /home/biocbuild/bbs-3.1-bioc/R/library/GenomicFeatures/extdata/GFF3_files/a.gff3
# Organism: NA
# miRBase build ID: NA
# Genome: NA
# transcript_nrow: 488
# exon_nrow: 1268
# cds_nrow: 1258
# Db created by: GenomicFeatures package from Bioconductor
# Creation time: 2015-09-21 19:13:17 -0700 (Mon, 21 Sep 2015)
# GenomicFeatures version at creation time: 1.20.4
# RSQLite version at creation time: 1.0.0
# DBSCHEMaversioN: 1.1
```

See `?makeTxDbFromGFF` in the [GenomicFeatures](#) package for more information.

Extract the exon coordinates grouped by gene from this gene model:

```
> exonsBy(txdb, by="gene")

GRangesList object of length 488:
$Solyc00g005000.2
GRanges object with 2 ranges and 2 metadata columns:
  seqnames      ranges strand |  exon_id      exon_name
  <Rle>      <IRanges>  <Rle> | <integer>      <character>

seqinfo: 1 sequence from an unspecified genome; no seqlengths
```

2.9 How to retrieve a gene model from AnnotationHub

When a gene model is not available as a *GRanges* or *GRangesList* object or as a *Bioconductor* data package, it may be available on [AnnotationHub](#). In this *HOWTO*, will look for a gene model for *Drosophila melanogaster* on [AnnotationHub](#). Create a 'hub' and then filter on *Drosophila melanogaster*:

```
> library(AnnotationHub)
> ### Internet connection required!
> hub <- AnnotationHub()
> hub <- subset(hub, hub$species=='Drosophila melanogaster')
```

There are 87 files that match *Drosophila melanogaster*. If you look at the metadata in *hub*, you can see that the 7th record represents a *GRanges* object from UCSC

```
> length(hub)
[1] 198
> head(names(hub))
[1] "AH79" "AH80" "AH81" "AH82" "AH83" "AH84"
> head(hub$title, n=10)
[1] "Drosophila_melanogaster.BDGP5.69.cdna.all.fa"
[2] "Drosophila_melanogaster.BDGP5.69.dna.toplevel.fa"
[3] "Drosophila_melanogaster.BDGP5.69.dna_rm.toplevel.fa"
[4] "Drosophila_melanogaster.BDGP5.69.dna_sm.toplevel.fa"
[5] "Drosophila_melanogaster.BDGP5.69.ncrna.fa"
[6] "Drosophila_melanogaster.BDGP5.69.pep.all.fa"
[7] "Assembly"
[8] "GDP Insertions"
[9] "BAC End Pairs"
[10] "FlyBase Genes"

> ## then look at a specific slice of the hub object.
> hub[7]

AnnotationHub with 1 record
# snapshotDate(): 2015-08-26
# names(): AH6789
# $dataprovder: UCSC
# $species: Drosophila melanogaster
# $rdataclass: GRanges
```

```
# $title: Assembly
# $description: GRanges object from on UCSC track Č  IAssembly
# $taxononyid: 7227
# $genome: dm3
# $sourcetype: UCSC track
# $sourceurl: rtracklayer://hgdownload.cse.ucsc.edu/goldenpath/dm3/d...
# $sourcedlastmodifieddate: NA
# $sourcesize: NA
# $tags: gold, UCSC, track, Gene, Transcript, Annotation
# retrieve record with 'object[["AH6789"]]'
```

So you can retrieve that dm3 file as a GRanges like this:

```
> gr <- hub[[names(hub)[7]]]
> summary(gr)
```

Length	Class	Mode
37688	GRanges	S4

The metadata fields contain the details of file origin and content.

```
> metadata(gr)
$trackLine
track name=gold description=gold visibility=1 url="NA"
```

Split the GRanges object by gene name to get a GRangesList object of transcript ranges grouped by gene.

```
> txbygn <- split(gr, gr$name)
```

You can now use txbygn with the summarizeOverlaps function to prepare a table of read counts for RNA-Seq differential gene expression.

Note that before passing txbygn to summarizeOverlaps, you should confirm that the seqlevels (chromosome names) in it match those in the BAM file. See ?renameSeqlevels, ?keepSeqlevels and ?seqlevels for examples of renaming seqlevels.

2.10 How to annotate peaks in read coverage

[coming soon...]

2.11 How to prepare a table of read counts for RNA-Seq differential gene expression

Methods for RNA-Seq gene expression analysis generally require a table of counts that summarize the number of reads that overlap or ‘hit’ a particular gene. In this HOWTO we count with the summarizeOverlaps function from the *GenomicAlignments* package and create a count table from the results.

Other packages that provide read counting are *Rsubread* and *easyRNASeq*. The *parathyroidSE* package vignette contains a workflow on counting and other common operations required for differential expression analysis.

As sample data we use the *pasillaBamSubset* data package described in the introduction.

```
> library(pasillaBamSubset)
> un1 <- untreated1_chr4() # single-end reads
```

summarizeOverlaps requires the name of a BAM file(s) and a gene model to count against. See introduction for a quick description of what a *gene models* is. The gene model must match the genome build the reads in the BAM file were aligned to. For the pasilla data this is dm3 Dmelanogaster which is available as a *Bioconductor* package. Load the package and extract the exon ranges grouped by gene:

```
> library(TxDb.Dmelanogaster.UCSC.dm3.ensGene)
> exbygene <- exonsBy(TxDb.Dmelanogaster.UCSC.dm3.ensGene, "gene")
```

exbygene is a *GRangesList* object with one list element per gene in the gene model.

`summarizeOverlaps` automatically sets a `yieldSize` on large BAM files and iterates over them in chunks. When reading paired-end data set the `singleEnd` argument to FALSE. See `?summarizeOverlaps` for details regarding the count modes and additional arguments.

```
> library(GenomicAlignments)
> se <- summarizeOverlaps(exbygene, un1, mode="IntersectionNotEmpty")
```

The return object is a *SummarizedExperiment* with counts accessible with the `assays` accessor:

```
> class(se)
[1] "SummarizedExperiment"
attr(,"package")
[1] "GenomicRanges"

> head(table(assays(se)$counts))
  0   1   2   3   4   5
15593 1   3   1   4   1
```

The count vector is the same length as `exbygene`:

```
> identical(length(exbygene), length(assays(se)$counts))
[1] TRUE
```

A copy of `exbygene` is stored in the `se` object and accessible with `rowRanges` accessor:

```
> rowRanges(se)

GRangesList object of length 15682:
$FBgn0000003
GRanges object with 1 range and 2 metadata columns:
  seqnames      ranges strand | exon_id exon_name
  <Rle>      <IRanges> <Rle> | <integer> <character>
 [1] chr3R [2648220, 2648518] + |     45123      <NA>
```

\$FBgn0000008

GRanges object with 13 ranges and 2 metadata columns:

	seqnames	ranges	strand		exon_id	exon_name
[1]	chr2R	[18024494, 18024531]	+		20314	<NA>
[2]	chr2R	[18024496, 18024713]	+		20315	<NA>
[3]	chr2R	[18024938, 18025756]	+		20316	<NA>
...
[11]	chr2R	[18059821, 18059938]	+		20328	<NA>
[12]	chr2R	[18060002, 18060339]	+		20329	<NA>
[13]	chr2R	[18060002, 18060346]	+		20330	<NA>

...

<15680 more elements>

seqinfo: 15 sequences (1 circular) from dm3 genome

Two popular packages for RNA-Seq differential gene expression are `DESeq` and `edgeR`. Tables of counts per gene are required for both and can be easily created with a vector of counts. Here we use the counts from our *SummarizedExperiment* object:

```
> library(DESeq)
> deseq <- newCountDataSet(assays(se)$counts, rownames(colData(se)))
> library(edgeR)
> edger <- DGEList(assays(se)$counts, group=rownames(colData(se)))
```

2.12 How to summarize junctions from a BAM file containing RNA-Seq reads

As sample data we use the *pasillaBamSubset* data package described in the introduction.

```
> library(pasillaBamSubset)
> un1 <- untreated1_chr4() # single-end reads
> library(GenomicAlignments)
> reads1 <- readGAlignments(un1)
> reads1

GAlignments object with 204355 alignments and 0 metadata columns:
  seqnames strand      cigar      qwidth     start      end
    <Rle> <Rle> <character> <integer> <integer> <integer>

 -----
 seqinfo: 8 sequences from an unspecified genome
```

For each alignment, the aligner generated a CIGAR string that describes its "geometry", that is, the locations of insertions, deletions and junctions in the alignment. See the SAM Spec available on the SAMtools website for the details (<http://samtools.sourceforge.net/>).

The `summarizeJunctions()` function from the *GenomicAlignments* package can be used to summarize the junctions in `reads1`.

```
> junc_summary <- summarizeJunctions(reads1)
> junc_summary

GRanges object with 910 ranges and 3 metadata columns:
  seqnames      ranges strand |      score plus_score
    <Rle>      <IRanges> <Rle> | <integer> <integer>

[909]      0
[910]      1
-----
seqinfo: 8 sequences from an unspecified genome
```

See `?summarizeJunctions` in the [GenomicAlignments](#) package for more information.

2.13 How to get the exon and intron sequences of a given gene

The exon and intron sequences of a gene are essentially the DNA sequences of the introns and exons of all known transcripts of the gene. The first task is to identify all transcripts associated with the gene of interest. Our sample gene is the human TRAK2 which is involved in regulation of endosome-to-lysosome trafficking of membrane cargo. The Entrez gene id is '66008'.

```
> trak2 <- "66008"
```

The [TxDb.Hsapiens.UCSC.hg19.knownGene](#) data package contains the gene model corresponding to the UCSC 'Known Genes' track.

```
> library(TxDb.Hsapiens.UCSC.hg19.knownGene)
> txdb <- TxDb.Hsapiens.UCSC.hg19.knownGene
```

The transcript ranges for all the genes in the gene model can be extracted with the `transcriptsBy` function from the [GenomicFeatures](#) package. They will be returned in a named `GRangesList` object containing all the transcripts grouped by gene. In order to keep only the transcripts of the TRAK2 gene we will subset the `GRangesList` object using the `[[` operator.

```
> library(GenomicFeatures)
> trak2_txs <- transcriptsBy(txdb, by="gene")[[trak2]]
> trak2_txs
```

`GRanges` object with 2 ranges and 2 metadata columns:

	seqnames	ranges	strand	tx_id	tx_name
	<Rle>	<IRanges>	<Rle>	<integer>	<character>
[1]	chr2	[202241930, 202316319]	-	12552	uc002uyb.4
[2]	chr2	[202259851, 202316319]	-	12553	uc002uyc.2

```
-----
seqinfo: 93 sequences (1 circular) from hg19 genome
```

`trak2_txs` is a `GRanges` object with one range per transcript in the TRAK2 gene. The transcript names are stored in the `tx_name` metadata column. We will need them to subset the extracted intron and exon regions:

```
> trak2_tx_names <- mcols(trak2_txs)$tx_name
> trak2_tx_names
[1] "uc002uyb.4" "uc002uyc.2"
```

The exon and intron genomic ranges for all the transcripts in the gene model can be extracted with the `exonsBy` and `intronsByTranscript` functions, respectively. Both functions return a `GRangesList` object. Then we keep only the exon and intron for the transcripts of the TRAK2 gene by subsetting each `GRangesList` object by the TRAK2 transcript names.

Extract the exon regions:

```
> trak2_exbytx <- exonsBy(txdb, "tx", use.names=TRUE) [trak2_tx_names]
> elementLengths(trak2_exbytx)

uc002uyb.4 uc002uyc.2
 16           8
```

... and the intron regions:

```
> trak2_inbytx <- intronsByTranscript(txdb, use.names=TRUE) [trak2_tx_names]
> elementLengths(trak2_inbytx)

uc002uyb.4 uc002uyc.2
 15           7
```

Next we want the DNA sequences for these exons and introns. The `getSeq` function from the `Biostrings` package can be used to query a `BSgenome` object with a set of genomic ranges and retrieve the corresponding DNA sequences.

```
> library(BSgenome.Hsapiens.UCSC.hg19)
```

Extract the exon sequences:

```
> trak2_ex_seqs <- getSeq(Hsapiens, trak2_exbytx)
> trak2_ex_seqs

2.14 How to get the CDS and UTR sequences of genes associated with colorectal cancer

In this *HOWTO* we extract the CDS and UTR sequences of genes involved in colorectal cancer. The workflow extends the ideas presented in the previous *HOWTO* and suggests an approach for identifying disease-related genes.

2.14.1 Build a gene list

We start with a list of gene or transcript ids. If you do not have pre-defined list one can be created with the *KEGG.db* and *KEGGgraph* packages. Updates to the data in the *KEGG.db* package are no longer available, however, the resource is still useful for identifying pathway names and ids.

Create a table of KEGG pathways and ids and search on the term ‘cancer’.

```
> library(KEGG.db)
> pathways <- toTable(KEGGPATHNAME2ID)
> pathways[grep("cancer", pathways$path_name, fixed=TRUE),]

  path_id          path_name
299  05200      Pathways in cancer
300  05210      Colorectal cancer
302  05212      Pancreatic cancer
303  05213      Endometrial cancer
305  05215      Prostate cancer
306  05216      Thyroid cancer
309  05219      Bladder cancer
312  05222      Small cell lung cancer
313  05223 Non-small cell lung cancer
```

Use the “05210” id to query the KEGG web resource (accesses the currently maintained data).

```
> library(KEGGgraph)
> dest <- tempfile()
> retrieveKGM("05200", "hsa", dest, "internal")
```

The suffix of the KEGG id is the Entrez gene id. The `translateKEGGID2GeneID` simply removes the prefix leaving just the Entrez gene ids.

```
> crids <- as.character(parseKGM2Dataframe(dest)[,1])
> crgenes <- unique(translateKEGGID2GeneID(crids))
> head(crgenes)

```

2.14.2 Identify genomic coordinates

The list of gene ids is used to extract genomic positions of the regions of interest. The Known Gene table from UCSC will be the annotation and is available as a *Bioconductor* package.

```
> library(TxDb.Hsapiens.UCSC.hg19.knownGene)
> txdb <- TxDb.Hsapiens.UCSC.hg19.knownGene
```

If an annotation is not available as a *Bioconductor* annotation package it may be available in [AnnotationHub](#). Additionally, there are functions in [GenomicFeatures](#) which can retrieve data from UCSC and Ensembl to create a TxDb. See `?makeTxDbFromUCSC` for more information.

As in the previous *HOWTO* we need to identify the transcripts corresponding to each gene. The transcript id (or name) is used to isolate the UTR and coding regions of interest. This grouping of transcript by gene is also used to re-group the final sequence results.

The `transcriptsBy` function outputs both the gene and transcript identifiers which we use to create a map between the two. The map is a `CharacterList` with gene ids as names and transcript ids as the list elements.

```
> txbygene <- transcriptsBy(txdb, "gene") ## subset on colorectal genes
> map <- relist(unlist(txbygene, use.names=FALSE)$tx_id, txbygene)
> map

IntegerList of length 239
[[["1630"]]] 64962 64963 64964
[[["836"]]] 20202 20203 20204
[[["842"]]] 4447 4448 4449 4450 4451 4452
[[["1499"]]] 13582 13583 13584 13585 13586 13587 13589
[[["51384"]]] 29319 29320 29321
[[["54361"]]] 4634 4635
[[["7471"]]] 46151
[[["7472"]]] 31279 31280
[[["7473"]]] 63770
[[["7474"]]] 16089 16090 16091 16092
...
<229 more elements>
```

Extract the UTR and coding regions.

```
> cds <- cdsBy(txdb, "tx")
> threeUTR <- threeUTRsByTranscript(txdb)
> fiveUTR <- fiveUTRsByTranscript(txdb)
```

Coding and UTR regions may not be present for all transcripts specified in `map`. Consequently, the subset results will not be the same length. This length discrepancy must be taken into account when re-listing the final results by gene.

```
> txid <- unlist(map, use.names=FALSE)
> cds <- cds[names(cds) %in% txid]
> threeUTR <- threeUTR[names(threeUTR) %in% txid]
> fiveUTR <- fiveUTR[names(fiveUTR) %in% txid]
```

Note the different lengths of the subset regions.

```
> length(txid) ## all possible transcripts
[1] 1045
> length(cds)
[1] 960
> length(threeUTR)
[1] 919
> length(fiveUTR)
[1] 947
```

These objects are GRangesLists with the transcript id as the outer list element.

```
> cds
GRangesList object of length 960:

-----
seqinfo: 93 sequences (1 circular) from hg19 genome
```

2.14.3 Extract sequences from BSgenome

The BSgenome packages contain complete genome sequences for a given organism.

Load the BSgenome package for homo sapiens.

```
> library(BSgenome.Hsapiens.UCSC.hg19)
> genome <- BSgenome.Hsapiens.UCSC.hg19
```

Use extractTranscriptSeqs to extract the UTR and coding regions from the BSgenome. This function retrieves the sequences for an any GRanges or GRangesList (i.e., not just transcripts like the name implies).

```
> threeUTR_seqs <- extractTranscriptSeqs(genome, threeUTR)
> fiveUTR_seqs <- extractTranscriptSeqs(genome, fiveUTR)
> cds_seqs <- extractTranscriptSeqs(genome, cds)
```

The return values are DNAStringSet objects.

```
> cds_seqs
A DNAStringSet instance of length 960
  width seq                                names
[1] 1119 ATGTTGGATGCCCTTGG...TGGCTGGACCAACCTGA 2043
[2]  900 ATGCGTTCAGTGGCGAG...TGGCTGGACCAACCTGA 2044
[3] 1176 ATGCTGAGACCGGGTGG...TGGCTGGACCAACCTGA 2045
...
[958]   681 ATGTTACGACAAGATTCC...CACAATGAATCAACGTAG 78103
[959]   768 ATGAGTGAAAGGTGACC...CACAATGAATCAACGTAG 78104
[960]   600 ATGAGTGAAAGGTGACC...CACAATGAATCAACGTAG 78105
```

Our final step is to collect the coding and UTR regions (currently organized by transcript) into groups by gene id. The relist function groups the sequences of a DNAStringSet object into a DNAStringSetList object, based on the specified skeleton argument. The skeleton must be a list-like object and only its shape (i.e. its element lengths) matters (its exact content is ignored). A simple form of skeleton is to use a partitioning object that we make by specifying the size of each partition. The partitioning objects are different for each type of region because not all transcripts had a coding or 3' or 5' UTR region defined.

```
> lst3 <- relist(threeUTR_seqs, PartitioningByWidth(sum(map %in% names(threeUTR))))
> lst5 <- relist(fiveUTR_seqs, PartitioningByWidth(sum(map %in% names(fiveUTR))))
> lstc <- relist(cds_seqs, PartitioningByWidth(sum(map %in% names(cds))))
```

There are 239 genes in map each of which have 1 or more transcripts. The table of element lengths shows how many genes have each number of transcripts. For example, 47 genes have 1 transcript, 48 genes have 2 etc.

```
> length(map)
[1] 239
> table(elementLengths(map))
 1  2  3  4  5  6  7  8  9 10 11 12 13 14 15 16 17 18 19 21 30
47 48 46 22 17 18 10  4  3  3  5  3  1  1  1  1  4  1  2  1  1
```

The lists of DNA sequences all have the same length as `map` but one or more of the element lengths may be zero. This would indicate that data were not available for that gene. The tables below show that there was at least 1 coding region available for all genes (i.e., none of the element lengths are 0). However, both the 3' and 5' UTR results have element lengths of 0 which indicates no UTR data were available for that gene.

```
> table(elementLengths(1stc))
 1  2  3  4  5  6  7  8  9 10 11 12 14 15 16 17 18 30
48 54 49 20 17 16  8  5  5  3  1  2  3  1  2  1  3  1

> table(elementLengths(1st3))
 0  1  2  3  4  5  6  7  8  9 11 12 13 14 15 16 17 18 30
2 49 56 47 19 18 13  9  5  8  2  2  2  1  1  2  1  1  1

> names(1st3)[elementLengths(1st3) == 0L] ## genes with no 3' UTR data
[1] "2255" "8823"

> table(elementLengths(1st5))
 0  1  2  3  4  5  6  7  8  9 10 11 12 14 15 16 17 18 30
3 48 52 49 19 17 16  8  5  5  3  2  2  3  1  1  1  3  1

> names(1st5)[elementLengths(1st5) == 0L] ## genes with no 5' UTR data
[1] "2255" "27006" "8823"
```

2.15 How to create DNA consensus sequences for read group ‘families’

The motivation for this *HOWTO* comes from a study which explored the dynamics of point mutations. The mutations of interest exist with a range of frequencies in the control group (e.g., 0.1% - 50%). PCR and sequencing error rates make it difficult to identify low frequency events (e.g., < 20%).

When a library is prepared with Nextera, random fragments are generated followed by a few rounds of PCR. When the genome is large enough, reads aligning to the same start position are likely descendant from the same template fragment and should have identical sequences.

The goal is to eliminate noise by grouping the reads by common start position and discarding those that do not exceed a certain threshold within each family. A new consensus sequence will be created for each read group family.

2.15.1 Sort reads into groups by start position

Load the BAM file into a `GAlignments` object.

```
> library(Rsamtools)
> bamfile <- system.file("extdata", "ex1.bam", package="Rsamtools")
> param <- ScanBamParam(what=c("seq", "qual"))
> library(GenomicAlignments)
> gal <- readGAlignments(bamfile, use.names=TRUE, param=param)
```

Use the `sequenceLayer` function to *lay* the query sequences and quality strings on the reference.

```
> qseq <- setNames(mcols(gal)$seq, names(gal))
> qual <- setNames(mcols(gal)$qual, names(gal))
> qseq_on_ref <- sequenceLayer(qseq, cigar(gal),
+                                from="query", to="reference")
> qual_on_ref <- sequenceLayer(qual, cigar(gal),
+                                from="query", to="reference")
```

Split by chromosome.

```
> qseq_on_ref_by_chrom <- splitAsList(qseq_on_ref, seqnames(gal))
> qual_on_ref_by_chrom <- splitAsList(qual_on_ref, seqnames(gal))
> pos_by_chrom <- splitAsList(start(gal), seqnames(gal))
```

For each chromosome generate one GRanges object that contains unique alignment start positions and attach 3 metadata columns to it: the number of reads, the query sequences, and the quality strings.

```
> gr_by_chrom <- lapply(seqlevels(gal),
+   function(seqname)
+ {
+   qseq_on_ref2 <- qseq_on_ref_by_chrom[[seqname]]
+   qual_on_ref2 <- qual_on_ref_by_chrom[[seqname]]
+   pos2 <- pos_by_chrom[[seqname]]
+   qseq_on_ref_per_pos <- split(qseq_on_ref2, pos2)
+   qual_on_ref_per_pos <- split(qual_on_ref2, pos2)
+   nread <- elementLengths(qseq_on_ref_per_pos)
+   gr_mcols <- DataFrame(nread=unname(nread),
+                          qseq_on_ref=unname(qseq_on_ref_per_pos),
+                          qual_on_ref=unname(qual_on_ref_per_pos))
+   gr <- GRanges(Rle(seqname, nrow(gr_mcols)),
+                 IRanges(as.integer(names(nread)), width=1))
+   mcols(gr) <- gr_mcols
+   seqlevels(gr) <- seqlevels(gal)
+   gr
+ })
```

Combine all the GRanges objects obtained in (4) in 1 big GRanges object:

```
> gr <- do.call(c, gr_by_chrom)
> seqinfo(gr) <- seqinfo(gal)
```

'gr' is a GRanges object that contains unique alignment start positions:

```
> gr[1:6]
```

GRanges object with 6 ranges and 3 metadata columns:

	seqnames	ranges	strand		nread	
	<Rle>	<IRanges>	<Rle>		<integer>	
[1]	seq1	[1, 1]	*		1	
[2]	seq1	[3, 3]	*		1	
[3]	seq1	[5, 5]	*		1	
[4]	seq1	[6, 6]	*		1	
[5]	seq1	[9, 9]	*		1	
[6]	seq1	[13, 13]	*		2	

	qseq_on_ref
	<DNAStringSetList>
[1]	CACTAGTGGCTCATTGTAATGTGTGGTTAACTCG
[2]	CTAGTGGCTCATTGTAATGTGTGGTTAACTCGT
[3]	AGTGGCTCATTGTAATGTGTGGTTAACTCGTCC
[4]	GTGGCTCATTGTAATTGGTTAACCTCTCT

Look at qseq_on_ref and qual_on_ref.

> *qseq_on_ref*

A DNAStringS

	width seq	names
[1]	36 CACTAGTGGCTCATTGTAATGTGTGGTTAACTCG	B7_591:4:96:693:509
[2]	35 CTAGTGGCTCATTGTAATGTGTGGTTAACTCGT	EAS54_65:7:152:36...
[3]	35 AGTGGCTCATTGTAATGTGTGGTTAACTCGTCC	EAS51_64:8:5:734:57
...	...	
[3269]	35 TTTTTCTTTTTTTTTTTTTTTGCATGCCA	EAS139_11:7:50:12...
[3270]	35 TTTTTTTTTTTTTTTTTTTGCATGCCAGAAA	EAS54_65:3:320:20...
[3271]	35 TTTTTTTTTTTTTTTTTGCATGCCAGAAA	EAS114_26:7:37:79...

> *qual_on_ref*

2 reads align to start position 13. Let's have a close look at their sequences:

```
> mcols(gr)$qseq_on_ref[[6]]
```

```
A DNASStringSet instance of length 2
width seq names
[1] 35 ATTGTAAATGTGTGGTTAACTCGTCCTGGCCCA EAS56_61:6:18:467...
[2] 36 ATTGTAAATGTGTGGTTAACTCGTCATGGCCAG EAS114_28:5:296:3...
```

and their qualities:

```
> mcols(gr)$qual_on_ref[[6]]
```

```
A BStringSet instance of length 2
  width seq names
[1]    35 <<<<<<;<<<8<<<<;8:;6/686&;(16666 EAS56_61:6:18:467...
[2]    36 <<<<;<<<;<;<<<<<<<<<8<8<3<8;<;<0; EAS114_28:5:296:3...
```

Note that the sequence and quality strings are those projected to the reference so the first letter in those strings are on top of start position 13, the 2nd letter on top of position 14, etc...

2.15.2 Remove low frequency reads

For each start position, remove reads with and under-represented sequence (e.g. threshold = 20% for the data used here which is low coverage). A unique number is assigned to each unique sequence. This will make future calculations easier and a little bit faster.

```
> qseq_on_ref <- mcols(gr)$qseq_on_ref
> tmp <- unlist(qseq_on_ref, use.names=FALSE)
> qseq_on_ref_id <- relist(match(tmp, tmp), qseq_on_ref)
```

Quick look at 'qseq_on_ref_id': It's an IntegerList object with the same length and "shape" as 'qseq_on_ref'.

```
> qseq_on_ref_id
IntegerList of length 1934
[[1]] 1
[[2]] 2
[[3]] 3
[[4]] 4
[[5]] 5
[[6]] 6 7
[[7]] 8
[[8]] 9
[[9]] 10 11
[[10]] 12
...
<1924 more elements>
```

Remove the under represented ids from each list element of 'qseq_on_ref_id':

```
> qseq_on_ref_id2 <- endoapply(qseq_on_ref_id,
+   function(ids) ids[countMatches(ids, ids) >= 0.2 * length(ids)])
```

Remove corresponding sequences from 'qseq_on_ref':

```
> tmp <- unlist(qseq_on_ref_id2, use.names=FALSE)
> qseq_on_ref2 <- relist(unlist(qseq_on_ref, use.names=FALSE)[tmp],
+   qseq_on_ref_id2)
```

2.15.3 Create a consensus sequence for each read group family

Compute 1 consensus matrix per chromosome:

```
> split_factor <- rep.int(seqnames(gr), elementLengths(qseq_on_ref2))
> qseq_on_ref2 <- unlist(qseq_on_ref2, use.names=FALSE)
> qseq_on_ref2_by_chrom <- splitAsList(qseq_on_ref2, split_factor)
> qseq_pos_by_chrom <- splitAsList(start(gr), split_factor)
> cm_by_chrom <- lapply(names(qseq_pos_by_chrom),
+   function(seqname)
+     consensusMatrix(qseq_on_ref2_by_chrom[[seqname]],
+       as.prob=TRUE,
+       shift=qseq_pos_by_chrom[[seqname]]-1,
+       width=seqlengths(gr)[[seqname]]))
> names(cm_by_chrom) <- names(qseq_pos_by_chrom)
```

'cm_by_chrom' is a list of consensus matrices. Each matrix has 17 rows (1 per letter in the DNA alphabet) and 1 column per chromosome position.

```
> lapply(cm_by_chrom, dim)
```

```
$seq1
[1] 18 1575
```

```
$seq2
[1] 18 1584
```

Compute the consensus string from each consensus matrix. We'll put "+" in the strings wherever there is no coverage for that position, and "N" where there is coverage but no consensus.

```
> cs_by_chrom <- lapply(cm_by_chrom,
+   function(cm) {
+     ## need to "fix" 'cm' because consensusString()
+     ## doesn't like consensus matrices with columns
+     ## that contain only zeroes (e.g., chromosome
+     ## positions with no coverage)
+     idx <- colSums(cm) == 0L
+     cm["+ ", idx] <- 1
+     DNAString(consensusString(cm, ambiguityMap="N"))
+   })
}
```

The new consensus strings.

```
> cs_by_chrom
$seq1
  1575-letter "DNAString" instance
seq: NANTAGNNNCTCANTTTAAANNTTNTTTTN...AATNATANNTTNTNTNTCTGNAC+++++
$seq2
  1584-letter "DNAString" instance
seq: +++++++++++++++++++++...NNNANANANANCTNNA++++++++++++++
```

2.16 How to compute binned averages along a genome

In some applications, there is the need to compute the average of a variable along a genome for a set of predefined fixed-width regions (sometimes called "bins"). One such example is coverage. Coverage is an RleList with one list element per chromosome. Here we simulate a coverage list.

```
> library(BSgenome.Scerevisiae.UCSC.sacCer2)
> set.seed(22)
> cov <- RleList(
+   lapply(seqlengths(Scerevisiae),
+         function(len) Rle(sample(-10:10, len, replace=TRUE))),
+   compress=FALSE)
> head(cov, 3)

RleList of length 3
$chrI
integer-Rle of length 230208 with 219146 runs
  Lengths:  1   1   1   1   1   1   1   1   ...   1   1   1   1   1   1   1
  Values : -4  -1   10   0    7    5    2   ...   4   -2   -8   1  -10   -8  -10

$chrII
integer-Rle of length 813178 with 774522 runs
  Lengths:  1   1   1   1   1   1   1   1   ...   1   1   1   2   2   1   1
  Values : -3  -6  -7  -3    9   -4  -10  ...  -3   -4   -5    2   -2   -8   0
```

```
$chrIII
integer-Rle of length 316617 with 301744 runs
Lengths: 1 1 1 1 1 1 1 ... 1 1 1 1 1 1 1 1
Values : 2 -3 -6 5 9 5 3 ... 4 -7 -10 -5 -10 -1 -3
```

Use the tileGenome function to create a set of bins along the genome.

```
> bins1 <- tileGenome(seqinfo(Scerevisiae), tilewidth=100,
+                      cut.last.tile.in.chrom=TRUE)
```

We define the following function to compute the binned average of a numerical variable defined along a genome.

Arguments:

- 'bins': a GRanges object representing the genomic bins.
Typically obtained by calling tileGenome() with
'cut.last.tile.in.chrom=TRUE'.
- 'numvar': a named RleList object representing a numerical
variable defined along the genome covered by 'bins', which
is the genome described by 'seqinfo(bins)'.
- 'mcolname': the name to give to the metadata column that will
contain the binned average in the returned object.

The function returns 'bins' with an additional metadata column named 'mcolname' containing the binned average.

```
> binnedAverage <- function(bins, numvar, mcolname)
+ {
+   stopifnot(is(bins, "GRanges"))
+   stopifnot(is(numvar, "RleList"))
+   stopifnot(identical(seqlevels(bins), names(numvar)))
+
+   ## A version of viewMeans() that pads "out of limits" views with zeros.
+   viewMeans2 <- function(v) {
+     means <- viewMeans(v)
+     w0 <- width(v)
+     w1 <- width(trim(v))
+     means <- means * w1 / w0
+     means[w0 != 0L & w1 == 0L] <- 0
+     means
+   }
+
+   bins_per_chrom <- split(ranges(bins), seqnames(bins))
+   means_list <- lapply(names(numvar),
+     function(seqname) {
+       v <- Views(numvar[[seqname]], bins_per_chrom[[seqname]])
+       viewMeans2(v)
+     })
+   new_mcol <- unsplit(means_list, as.factor(seqnames(bins)))
+   mcols(bins)[[mcolname]] <- new_mcol
+   bins
+ }
```

Compute the binned average for 'cov':

```
> bins1 <- binnedAverage(bins1, cov, "binned_cov")
> bins1
```

GRanges object with 121639 ranges and 1 metadata column:

seqnames	ranges	strand	binned_cov
<code><Rle></code>	<code><IRanges></code>	<code><Rle></code>	<code><numeric></code>

```
[1] chrI [ 1, 100] * | -0.66
[2] chrI [101, 200] * | -0.05
[3] chrI [201, 300] * | -1.56
...
[121637] 2micron [6101, 6200] * | -0.25
[121638] 2micron [6201, 6300] * | -0.54
[121639] 2micron [6301, 6318] * | -0.4444444444444444
-----
seqinfo: 18 sequences (2 circular) from sacCer2 genome
```

The bin size can be modified with the `tilewidth` argument to `tileGenome`. For additional examples see `?tileGenome`.

3 Session Information

```
R version 3.2.2 (2015-08-14)
Platform: x86_64-pc-linux-gnu (64-bit)
Running under: Ubuntu 14.04.3 LTS
```

```
locale:
