

# Package ‘clinfun’

July 22, 2025

**Title** Clinical Trial Design and Data Analysis Functions

**Version** 1.1.5

**Depends** R (>= 3.0.0), graphics, stats

**Imports** mvtnorm

**Suggests** knitr, rmarkdown, survival

**Author** Venkatraman E. Seshan [aut, cre],  
Karissa Whiting [aut]

**Description** Utilities to make your clinical collaborations easier if not fun. It contains functions for designing studies such as Simon 2-stage and group sequential designs and for data analysis such as Jonckheere-Terpstra test and estimating survival quantiles.

**Maintainer** Venkatraman E. Seshan <seshanv@mskcc.org>

**License** GPL (>= 2)

**NeedsCompilation** yes

**VignetteBuilder** knitr

**Repository** CRAN

**Date/Publication** 2023-10-19 19:40:05 UTC

aucVardiTest	<i>Two-Sample Tests for Growth Curves under Dependent Right Censoring</i>
--------------	---

---

## Description

Permutation test for comparing growth curves across tow groups under dependent right censoring.

## Usage

```
aucVardiTest(meas, grp, tim=NULL, cgrps=NULL, nperm=5000)
```

## Arguments

meas	Matrix of measurements where the rows are the subjects and columns the time-points. At least one value should not be missing in each row. For example they can be tumor sizes measured over time.
grp	Group indicator for each subject. There must be at least two different groups. This can represent each subject's treatment.
tim	Times at which the measurements in meas are taken. If missing, the times are set to 1 through ncol(meas).
cgrps	The two groups that are being compared. If missing the first two groups will be compared.
nperm	Number of permutations for the reference distribution.

## Details

The test statistic is defined as the sum of pairwise differences in the partial areas under the growth curve. For each pair of subjects the partial area is computed until the smaller of the maximum followup times. For each subject, linear interpolation is used to fill-in missing values prior to the maximum followup time. The reference distribution of obtained by permuting the group labels.

**Value**

returns a list with objects `ostat`, `pstat` and `p.value` which are the observed test statistic for the two groups being compared, values of the statistics when the group labels are permuted

**References**

Vardi Y., Ying Z. and Zhang C.H. (2001). Two-Sample Tests for Growth Curves under Dependent Right Censoring. *Biometrika* 88, 949-960.

**Examples**

```
grp <- sample(1:3, 100, replace=TRUE)
grp0 <- LETTERS[grp]
maxfup <- sample(5:20, 100, replace=TRUE)
meas <- matrix(NA, 100, 20)
for(i in 1:100) {
  meas[i, 1:maxfup[i]] <- cumsum((3+0.04*grp[i]) + rnorm(maxfup[i]))
}
aucVardiTest(meas, grp)
aucVardiTest(meas, grp0, cgrps=c("C","B"))
```

---

`calogrank`*Survival curves analysis of covariance*

---

**Description**

Logrank test to compare survival curves adjusting for covariates

**Usage**

```
calogrank(ftime, fstatus, grp, cvt, strat=NULL)
```

**Arguments**

<code>ftime</code>	failure times
<code>fstatus</code>	status indicator
<code>grp</code>	group indicator
<code>cvt</code>	continuous covariates used for adjusted analysis
<code>strat</code>	stratification variable

**Details**

`calogrank` is the covariate adjusted version of k-sample `survdiff`. The function in its current form only does basic error checking.

## References

Heller G. and Venkatraman E.S. (2004) A nonparametric test to compare survival distributions with covariate adjustment. *JRSS-B* 66, 719-733.

## Examples

```
## Not run:  library(survival)
data(pbc)
pbc1 <- pbc
pbc1$trt[pbc1$trt == -9] <- NA
pbc1$copper[pbc1$copper == -9] <- NA
# only death (2) is considered; transplant(1) is censored
calogrank(pbc1$time, pbc1$status==2, pbc1$trt, pbc1[,c("copper")])
calogrank(pbc1$time, pbc1$status==2, pbc1$trt,
          pbc1[,c("protime", "copper")])
## End(Not run)
```

---

coxphCPE

*Concordance Probability Estimate for Cox model*

---

## Description

Calculates the Concordance Probability Estimate for a Cox proportional hazards model. Both the Gonen and Heller (2005) version for continuous risk score and Heller and Mo (2016) for discrete risk score can be calculated.

## Usage

```
coxphCPE(phfit, out.ties=FALSE)
```

## Arguments

phfit            output from a proportional hazards fit.  
 out.ties        binary flag to decide if pairs with tied risk scores should be used.

## Value

coxphCPE returns a vector with CPE, smooth.CPE and se.CPE which are the estimate, the smoothed estimate and its standard error respectively.

## References

Gonen M and Heller G. (2005) Concordance probability and discriminatory power in proportional hazards regression. *Biometrika* 92, 965-970.

Heller G and Mo Q. (2016). Estimating the concordance probability in a survival analysis with a discrete number of risk groups. *Lifetime Data Analysis*, 22,263-79.

**Examples**

```
## Not run: library(survival)
data(pbc)
pbcfit <- coxph(Surv(time, status==2) ~ trt + log(copper), pbc,
  subset=(trt>0 & copper>0))
coxphCPE(pbcfit)

## End(Not run)
```

---

coxphERR

*Heller Explained Relative Risk*

---

**Description**

Calculates the contribution of a subset of covariates to the explained relative risk derived from the full Cox proportional hazards model.

**Usage**

```
coxphERR(phfit, ngamma=NULL)
```

**Arguments**

phfit	The output from a proportional hazards fit.
ngamma	A vector of indices corresponding to covariates of interest. If missing (default), the explained relative risk is computed for the full model.

**Details**

The object phfit should be the result of a call to coxph with the option x=TRUE.

**Value**

The function coxphERR returns the vector (ERR, se.ERR). The first component ERR represents the contribution of a subset of covariates to the explained relative risk estimate of the full model. If a set of covariates is not provided, then it computes the estimate of the full model. The second component se.ERR is the standard error of the estimate.

**References**

Heller G. (2012) A measure of explained risk in the proportional hazards model. *Biostatistics*

**Examples**

```
## Not run:
library(survival)
ovarianfit <- coxph(Surv(futime, fustat) ~ age + resid.ds + rx +
                    ecog.ps, data=ovarian,x=T)
# Compute the explained relative risk (ERR) and
# its standard error (se.ERR) for the full model.
coxphERR(ovarianfit)
# Compute the contribution of age and ECOG performance status to
# the explained relative risk. Age and ECOG performance status are
# the first and fourth covariates in the model.
coxphERR(ovarianfit, c(1,4))

## End(Not run)
```

---

coxphQuantile	<i>Survival time quantile as a function of covariate</i>
---------------	--

---

**Description**

Draws a quantile curve of survival distribution as a function of covariate.

**Usage**

```
coxphQuantile(phfit, xrange, p=0.5, whichx=1, otherx=NULL, ...)
```

**Arguments**

phfit	output from a proportional hazards fit.
xrange	the range of covariate values for which the quantiles of survival times are computed.
p	the probability level for the quantile (default is median).
whichx	if there are more than one covariates in the Cox model, the one chosen for the quantile plot.
otherx	the values for other covariates in the Cox model. If missing uses their average values.
...	additional parameters to be passed on to the lines command.

**Details**

This function is used to draw quantile curves. It requires a plot of the data (time & covariate of interest) to be present. See example.

It invisibly returns the observed failure times and the covariate values at which the estimated survival probability is (exactly) p.

## References

Heller G. and Simonoff J.S. (1992) Prediction in censored survival data: A comparison of the proportional hazards and linear regression models. *Biometrics* 48, 101-115.

## Examples

```
## Not run:  library(survival)
data(pbc)
pbcfit <- coxph(Surv(time, status==2) ~ trt + log(copper), pbc,
               subset=(trt>0 & copper>0))
plot(log(pbc$copper[pbc$trt>0 & pbc$copper>0]), pbc$time[pbc$trt>0 &
  pbc$copper>0], pch=c("o","x")[1+pbc$status[pbc$trt>0 & pbc$copper>0]],
     xlab="log Copper", ylab="Survival time")
coxphQuantile(pbcfit, c(2.5,6), whichx=2, otherx=1)
coxphQuantile(pbcfit, c(2.5,6), p=0.75, whichx=2, otherx=2, col=2)
## End(Not run)
```

---

deltaAUC

*Comparing the AUC from ROC curves from nested binary regression*

---

## Description

Conducts the test

## Usage

```
deltaAUC(y, x, z)
```

## Arguments

y	binary response variable
x	matrix of set of covariates that is the basis of the existing (reduced) model
z	matrix of set of covariates that are added to to get the new (full) model

## Details

The models are fit using maximum rank correlation (MRC) method which is an alternate approach to logistic regression. In MRC the area under the ROC curve (AUC) is maximized as opposed to the likelihood in logistic regression. Due to invariance of AUC to location and scale shifts one of the parameters (anchor variable) is set to 1.

The first variable (column) in x is used as the anchor variable.

The IPMN data set used as an example in the paper below is included. The columns are high risk lesion (V1), recent weight loss (V2), main duct involvement (V4), presence of a solid component in imaging (V3), and lesion size (V5).

**Value**

It returns a list with the following elements

<code>par.full</code>	the MRC estimate of parameters for the full model
<code>par.red</code>	the MRC estimate of parameters for the reduced model
<code>results</code>	matrix of results which gives the full reduced model AUCs along with the test statistic and p-value

**References**

Heller G., Seshan V.E., Moskowitz C.S. and Gonen M. (2016) Inference for the difference in the area under the ROC curve derived from nested binary regression models. *Biostatistics* 18, 260-274.

**Examples**

```
data(ipmn)
deltaAUC(ipmn$V1, cbind(ipmn$V4, ipmn$V3, ipmn$V5), ipmn$V2)
```

---

fedesign

*Trial Designs Based On Fisher's Exact Test*

---

**Description**

Calculates sample size, effect size and power based on Fisher's exact test

**Usage**

```
fe.ssize(p1, p2, alpha=0.05, power=0.8, r=1, npm=5, mmax=1000)
CPS.ssize(p1, p2, alpha=0.05, power=0.8, r=1)
fe.mdor(ncase, ncontrol, pcontrol, alpha=0.05, power=0.8)
mdrr(n, cprob, presp, alpha=0.05, power=0.8, niter=15)
fe.power(d, n1, n2, p1, alpha = 0.05)
or2pcase(pcontrol, OR)
```

**Arguments**

<code>p1</code>	response rate of standard treatment
<code>p2</code>	response rate of experimental treatment
<code>d</code>	difference = $p_2 - p_1$
<code>pcontrol</code>	control group probability
<code>n1</code>	sample size for the standard treatment group
<code>n2</code>	sample size for the standard treatment group
<code>ncontrol</code>	control group sample size
<code>ncase</code>	case group sample size

alpha	size of the test (default 5%)
power	power of the test (default 80%)
r	treatments are randomized in 1:r ratio (default r=1)
npm	the sample size program searches for sample sizes in a range (+/- npm) to get the exact power
mmax	the maximum group size for which exact power is calculated
n	total number of subjects
cprob	proportion of patients who are marker positive
presp	probability of response in all subjects
niter	number of iterations in binary search
OR	odds-ratio

## Details

CPS.ssize returns Casagrande, Pike, Smith sample size which is a very close to the exact. Use this for small differences  $p_2 - p_1$  (hence large sample sizes) to get the result instantaneously.

Since Fisher's exact test orders the tables by their probability the test is naturally two-sided.

fe.ssize return a 2x3 matrix with CPS and Fisher's exact sample sizes with power.

fe.mdor return a 3x2 matrix with Schlesselman, CPS and Fisher's exact minimum detectable odds ratios and the corresponding power.

fe.power returns a Kx2 matrix with probabilities ( $p_2$ ) and exact power.

mdrr computes the minimum detectable  $P(\text{resplmarker}^+)$  and  $P(\text{resplmarker}^-)$  configurations when total sample size (n),  $P(\text{response})$  (presp) and proportion of subjects who are marker positive (cprob) are specified.

or2pcase give the probability of disease among the cases for a given probability of disease in controls ( $p_{\text{control}}$ ) and odds-ratio (OR).

## References

Casagrande, JT., Pike, MC. and Smith PG. (1978). An improved approximate formula for calculating sample sizes for comparing two binomial distributions. *Biometrics* 34, 483-486.

Fleiss, J. (1981) *Statistical Methods for Rates and Proportions*.

Schlesselman, J. (1987) Re: Smallest Detectable Relative Risk With Multiple Controls Per Case. *Am. J. Epi.*

**Description**

Functions to calculate sample size for group sequential designs

**Usage**

```
gsdesign.binomial(ifrac, pC, pE, r = 1, sig.level = 0.05, power = 0.8,
  delta.eb=0.5, delta.fb = NULL, alternative = c("two.sided",
  "one.sided"), pooled.variance = FALSE, CPS = TRUE, tol=0.00001, ...)
gsdesign.normal(ifrac, delta, sd = 1, r = 1, sig.level = 0.05,
  power = 0.8, delta.eb = 0.5, delta.fb = NULL, alternative =
  c("two.sided", "one.sided"), tol=0.00001, ...)
gsdesign.survival(ifrac, haz.ratio, r = 1, sig.level = 0.05,
  power = 0.8, delta.eb = 0.5, delta.fb = NULL, alternative =
  c("two.sided", "one.sided"), tol=0.00001, ...)
```

**Arguments**

ifrac	information fraction or the ratio of current sample size or number of events to the total sample size or number of events. This should be an increasing vector of numbers from 0 to 1 with the last one being 1. If just 1 is given a fixed sample design is derived.
pC	prob of success of the standard therapy (for binomial data)
pE	prob of success of the experimental therapy (for binomial data)
delta	true difference in means (for normal data)
sd	standard deviation (for normal data)
haz.ratio	hazard ratio (for survival comparison)
r	treatment allocation of r (default=1) experimental per 1 control.
sig.level	significance level (type I error probability)
power	power of test (1 minus type II error probability)
delta.eb	power for efficacy boundary in the Pocock (=0) to O'Brien-Fleming (=0.5) family (default is 0.5)
delta.fb	power for futility boundary in the Pocock (=0) to O'Brien-Fleming (=0.5) family (default is NULL i.e. no futility boundary is requested.)
alternative	one- or two-sided test.
pooled.variance	whether the test statistic is standardized by pooled ( $2 \cdot \bar{p} \cdot (1 - \bar{p})$ ) or un-pooled variance ( $pC \cdot (1 - pC) + pE \cdot (1 - pE)$ ). Default is un-pooled variance.
CPS	whether continuity correction is used for sample size calculation as in Casagrande, Pike & Smith. Default is to use it.
tol	tolerance level for multivariate normal probability computation.
...	additional options passed on the pmvnorm function.

## Details

The futility boundary is not returned when delta.fb is not specified i.e. stopping for futility is not requested. The futility boundary is non-binding. That is the significance level is not adjusted to account for early stopping for futility. This makes the test a bit conservative in that the true size is less than the nominal level.

If the alternative is two-sided by default the futility boundary will also be two-sided i.e. continuation region is wedge shaped. However, if the goal is to show the superiority of the experimental treatment then futility boundary should be one sided. This can be achieved by deriving the boundaries for one-sided alternative and significance level set at half of the value used for two sided alternative. See the examples section for a representative design for which the trial cannot be stopped at the first look for futility.

The Casagrande-Pike-Smith type continuity correction is obtained using the formula

$$n * [1 + \sqrt{1 + 4/(|pC - pE| * n)}]^2$$

where n is the uncorrected sample size.

## Value

a list with ifrac, sig.level, power, alternative, delta.eb, delta.fb and:

efbdry	the critical value to use at the different looks. For two-sided alternative the absolute test statistic should exceed this.
futbdry	the critical value to use at the different looks. For two-sided alternative the absolute test statistic should be below this.
sample.size	the sample size per arm for binomial/normal data.
num.events	the total number of failures which should be converted to number of subjects using censoring proportion.

## Examples

```
gsdesign.normal(1:4/4, 0.25, sig.level=0.05, alt="t", delta.fb=0.5)
gsdesign.normal(1:4/4, 0.25, sig.level=0.025, alt="o", delta.fb=0.5)
```

---

jonckheere.test	<i>Exact/permutation version of Jonckheere-Terpstra test</i>
-----------------	--

---

## Description

Jonckheere-Terpstra test to test for ordered differences among classes

## Usage

```
jonckheere.test(x, g, alternative = c("two.sided", "increasing",
  "decreasing"), nperm=NULL)
```

**Arguments**

x, g	data and group vector
alternative	means are monotonic (two.sided), increasing, or decreasing
nperm	number of permutations for the reference distribution. The default is null in which case the permutation p-value is not computed. Recommend that the user set nperm to be 1000 or higher if permutation p-value is desired.

**Details**

jonckheere.test is the exact (permutation) version of the Jonckheere-Terpstra test. It uses the statistic

$$\sum_{k < l} \sum_{ij} I(X_{ik} < X_{jl}) + 0.5I(X_{ik} = X_{jl}),$$

where  $i, j$  are observations in groups  $k$  and  $l$  respectively. The asymptotic version is equivalent to `cor.test(x, g, method="k")`. The exact calculation requires that there be no ties and that the sample size is less than 100. When data are tied and sample size is at most 100 permutation p-value is returned.

**References**

Terpstra, T. J. (1952). The asymptotic normality and consistency of Kendall's test against trend, when ties are present in one ranking. *Indagationes Mathematicae* 14:327-333.

**Examples**

```
set.seed(1234)
g <- rep(1:5, rep(10,5))
x <- rnorm(50)
jonckheere.test(x+0.3*g, g)
x[1:2] <- mean(x[1:2]) # tied data
jonckheere.test(x+0.3*g, g)
jonckheere.test(x+0.3*g, g, nperm=5000)
```

---

ktau

*Kendall's tau-b estimate*

---

**Description**

Calculates the Kendall's tau-b.

**Usage**

```
ktau(x, y)
```

**Arguments**

x	first variable
y	second variable

**Details**

ktau computes the same quantity as `cor(x, y, method="kendall")`. It uses a faster algorithm than pairwise comparisons used by `cor`.

**Value**

ktau returns Kendall's tau-b.

**Examples**

```
set.seed(1234)
x <- rnorm(10000); y <- x+rnorm(10000)
cor(x, y, method="k")
clinfun:::ktau(x,y)
```

---

oc.twostage.bdry      *Two-stage boundary operating characteristics*

---

**Description**

Calculates the operating characteristics of a two-stage boundary.

**Usage**

```
oc.twostage.bdry(pu, pa, r1, n1, r, n)
```

**Arguments**

pu	unacceptable response rate
pa	response rate that is desirable
r1	first stage threshold to declare treatment undesirable
n1	first stage sample size
r	overall threshold to declare treatment undesirable
n	total sample size

**Value**

oc.twostage.bdry returns the type I and II error rates as well as the probability of early termination and expected sample size under pu for a specific boundary.

---

permlogrank	<i>Permutation version of survdiff</i>
-------------	--

---

**Description**

Small sample survdiff using permutation reference distributions.

**Usage**

```
permlogrank(formula, data, subset, na.action, rho=0, nperm=5000)
```

**Arguments**

nperm	number of permutations for the reference distribution
formula, data, subset, na.action, rho	see survdiff for details

**Details**

permlogrank is the permutation version of k-sample survdiff. see survdiff in survival package for details.

**References**

Heller G, Venkatraman ES. (1996). Resampling procedures to compare two survival distributions in the presence of right censored data. *Biometrics* 52:1204-1213.

---

ph2simon	<i>Simon's 2-stage Phase II design</i>
----------	--

---

**Description**

Calculates Optimal and Minimax 2-stage Phase II designs given by Richard Simon

**Usage**

```
ph2simon(pu, pa, ep1, ep2, nmax=100)
## S3 method for class 'ph2simon'
print(x, ...)
## S3 method for class 'ph2simon'
plot(x, ...)
```

**Arguments**

pu	unacceptable response rate; baseline response rate that needs to be exceeded for treatment to be deemed promising
pa	response rate that is desirable; should be larger than pu
ep1	threshold for the probability of declaring drug desirable under pu (target type 1 error rate); between 0 and 1
ep2	threshold for the probability of rejecting the drug under pa (target type 2 error rate); between 0 and 1
nmax	maximum total sample size (default 100; can be at most 1000)
x	object returned by ph2simon
...	arguments to be passed onto plot and print commands called within

**Value**

ph2simon returns a list with pu, pa, alpha, beta and nmax as above and:

out	matrix of best 2 stage designs for each value of total sample size n. The 6 columns in the matrix are:
	r1 number of responses needed to exceeded in first stage
	n1 number of subjects treated in first stage
	r number of responses needed to exceeded at the end of trial
	n total number of subjects to be treated in the trial
	EN(pu) expected number pf patients in the trial under pu
	PET(pu) probability of stopping after the first stage under pu

Trial is stopped early if  $\leq r1$  responses are seen in the first stage and treatment is considered desirable only when  $>r$  responses seen.

**Methods (by generic)**

- `print(ph2simon)`: formats and returns the minimax, optimal and any admissible designs.
- `plot(ph2simon)`: plots the expected sample size against the maximum sample size as in Jung et al., 2001

**See Also**

[twostage.inference](#), [oc.twostage.bdry](#)

**Examples**

```
ph2simon(0.2, 0.4, 0.1, 0.1)
ph2simon(0.2, 0.35, 0.05, 0.05)
ph2simon(0.2, 0.35, 0.05, 0.05, nmax=150)
```

---

ph2single	<i>Exact single stage Phase II design</i>
-----------	---

---

**Description**

Calculates the exact one stage Phase II design

**Usage**

```
ph2single(pu,pa,ep1,ep2,nsoln=5)
```

**Arguments**

pu	unacceptable response rate
pa	response rate that is desirable
ep1	threshold for the probability of declaring drug desirable under p0
ep2	threshold for the probability of rejecting the drug under p1
nsoln	number of designs with given alpha and beta

**Value**

ph2single returns a data frame with variables: n, r, and the Type I and Type II errors. Treatment desirable if >r respenses seen.

---

power.ladesign	<i>Power of k-sample rank test under Lehmann alternative</i>
----------------	--

---

**Description**

Functions to calculate the power of rank tests for animal studies.

**Usage**

```
power.ladesign(gsize, odds.ratio, sig.level = 0.05, statistic =
  c("Kruskal-Wallis", "Jonckheere-Terpstra"), alternative =
  c("two.sided", "one.sided"), nrep=1e+6)
## S3 method for class 'ladesign'
print(x,...)
```

**Arguments**

gsize	sample size of the k (= length of vector) groups.
odds.ratio	odds ratio parameters for the k-1 groups. The first group is considered the control.
sig.level	the significance level of the test (default = 0.05)
statistic	the test statistic for the k-group comparison. Is one of Kruskal-Wallis (default) or Jonckheere-Terpstra.
alternative	one- or two-sided test. Valid only for the Jonckheere-Terpstra test.
nrep	number of reps (default 1 million) for Monte Carlo.
x	object of class ladesign returned by power.ladesign
...	arguments to be passed on left for S3 method consistency.

**Details**

Although the power for Jonckheere-Terpstra test is calculated for any set of odds ratio, the test is meant for monotone alternative. Thus it is preferable to specify odds ratios that are monotonically increasing with all values larger than 1 or decreasing with all values smaller than 1.

**Value**

returns a list with objects group.size, odds.ratio, statistic, sig.level and power. The "print" method formats the output.

**References**

Heller G. (2006). Power calculations for preclinical studies using a K-sample rank test and the Lehmann alternative hypothesis. *Statistics in Medicine* 25, 2543-2553.

**Examples**

```
power.ladesign(c(9,7), 4, statistic="K")
power.ladesign(c(9,7,9), c(2,4), statistic="J")
power.ladesign(c(9,7,9), c(2,4), statistic="J", alt="o")
```

---

pselect

*Probability of selection under pick the winner rule*

---

**Description**

Calculates the probability of selecting the treatment with the higher response rate under the pick the winner rule.

**Usage**

```
pselect(n, p, min.diff=NULL, min.resp=NULL)
```

**Arguments**

n	sample size for each treatment arm. This is either a single integer or a vector of two integers for the special case of comparing two treatments with unequal sample sizes
p	vector of response rates for the treatments.
min.diff	this is the number of responses or the rate by which the best treatment should be superior to the others to be chosen. This must be a positive integer or a rate between 0 and 1. If missing it defaults to 1 for the equal sample size case but quits with a warning for the unequal sample size case.
min.resp	the minimum number of responses in each treatment arm for it to be considered further. If missing defaults to 0.

**Value**

the function returns a list with:

prob.none.worthy	is the probability that no treatment has the minimum number of responses specified in min.resp. this element is present only if min.resp is greater than 0 for at least one arm.
prob.inconclusive	this is the probability that the best treatment has the requisite min.resp responses but exceeds the second best by less than min.diff responses (rate) provided the second best also has at least min.resp responses.
prob.selection	this is a matrix which for each treatment gives the response probability and the probability of selecting it i.e. the number of responses in the chosen arm is at least min.resp and either none of the remaining arms exceed the min.resp threshold or the chosen (best) arm is better than the second best by at least min.diff responses (rate).

**References**

Simon R, Wittes RE, Ellenberg SS. (1985). Randomized phase II clinical trials. *Cancer Treat Rep* 69, 1375-1381.

**Examples**

```
# selection when no difference i.e. type I error
pselect(18, c(0.2, 0.2, 0.2))
# selection probability
pselect(18, c(0.2, 0.2, 0.4))
pselect(26, c(0.2, 0.2, 0.4), min.diff=2, min.resp=3)
# unequal sample size case
pselect(c(27,54), c(0.5, 0.65), min.diff=0.05)
# unequal sample size case
pselect(c(27,54), c(0.5, 0.65), min.diff=0.05, min.resp=c(14,27))
```

---

roc.area.test	<i>Nonparametric area under the ROC curve</i>
---------------	---

---

### Description

Computes the nonparametric area under the ROC curve and its variance based on U-statistic theory (DDCP).

### Usage

```
roc.area.test(markers, status)
## S3 method for class 'roc.area.test'
print(x, ...)
```

### Arguments

markers	The marker values for each subject. If there are more than one markers then this should be a matrix.
status	binary disease status indicator
x	object of class roc.area.test output from this function.
...	optional arguments to the print function.

### Details

It calculates the area and its variance. For more than one marker it calculates the statistic to test for the equality of all AUCs. This statistic has a standard normal reference distribution for two variables and chi-square with number of variables minus 1.

### Value

a list with the following elements

area	estimated area.
var	estimated variance (matrix).
stat	test statistic for equality of AUCs. Is not returned when only one diagnostic marker is present.
p.value	the p-value for the test of equality (2-sided).
df	the degrees of freedom of the chi-square.

The "print" method formats and returns the output.

### References

DeLong, E. R., D. M. DeLong, and D. L. Clarke-Pearson. 1988. Comparing the areas under two or more correlated receiver operating characteristic curves: A nonparametric approach. *Biometrics* 44:837-845.

**Examples**

```

g <- rep(0:1, 50)
x <- rnorm(100) + g
y <- rnorm(100) + g
z <- rnorm(100) + g
roc.area.test(cbind(x,y), g)
roc.area.test(cbind(x,y,z), g)
y1 <- y + 0.75*g
roc.area.test(cbind(x,y1), g)

```

---

roc.curve

*Empirical ROC curve*

---

**Description**

Computes the empirical ROC curve for a diagnostic tool.

**Usage**

```

roc.curve(marker, status, method=c("empirical"))
## S3 method for class 'roc.curve'
print(x, ...)
## S3 method for class 'roc.curve'
plot(x, PRC=FALSE, ...)
## S3 method for class 'roc.curve'
lines(x, PRC=FALSE, ...)

```

**Arguments**

marker	the marker values for each subject.
status	binary disease status indicator
method	the method for estimating the ROC curve. Currently only the empirical curve is implemented.
x	object of class roc.area.test output from this function.
PRC	flag to tell whether ROC or Precision-Recall curve plotted.
...	optional arguments to the print, plot and lines functions.

**Details**

The computation is based on assuming that larger values of the marker is indicative of the disease. So for a given threshold  $x_0$ , TPR is  $P(\text{marker} \geq x_0 | \text{status} = 1)$  and FPR is  $P(\text{marker} \geq x_0 | \text{status} = 0)$ . This function computes the empirical estimates of TPR and FPR.

**Value**

a list with the following elements

marker	the diagnostic marker being studied.
status	binary disease
tpr	true positive rates for all thresholds.
fpr	true positive rates for all thresholds.
ppv	positive predictive values for all thresholds.
npv	negative predictive values for all thresholds.

The "print" method returns the nonparametric AUC and its s.e.

The "plot" and "lines" methods can be used to draw a new plot and add to an existing plot of ROC curve.

**Examples**

```
g <- rep(0:1, 50)
x <- rnorm(100) + g
y <- rnorm(100) + 1.5*g
o <- roc.curve(x, g)
plot(o)
lines(roc.curve(y, g), col=2)
```

---

roc.perm.test	<i>Permutation test to compare ROC curve</i>
---------------	--

---

**Description**

Computes the test statistic and permutation reference distribution for comparing paired or unpaired ROC curves.

**Usage**

```
roc.perm.test(marker, status, marker2=NULL, group=NULL,
              nperm=2500, mp=NULL)
## S3 method for class 'roc.perm.test'
print(x, ...)
## S3 method for class 'roc.perm.test'
plot(x, ...)
```

**Arguments**

marker	marker values for each subject.
status	binary disease status indicator.
marker2	second diagnostic marker for the same subjects (paired).
group	indicator of which diagnostic test was used (unpaired).
nperm	number of permutations for the reference distribution.
mp	mixing proportion for the unpaired case when proportion of diseased subjects can differ.
x	object of class roc.perm.test output from this function.
...	optional arguments to print and plot functions.

**Details**

This function implements the permutation method described in the Venkatraman and Begg (1996) paper for the paired case and the Venkatraman (2000) paper for the unpaired case.

The function detects whether the data are paired or unpaired by testing which of the options marker2 and group is specified. If both are missing it will stop with an error message. At present exactly one should be missing.

**Value**

an object of class roc.perm.test with the following elements

ostat	test statistic from the observed data.
pstat	test statistic from permuted data.
p.value	the p-value for the test of equality (2-sided).

The "print" method formats and returns the statistic and p-value. The "plot" method plots the density from the permutation reference distribution and marks the location of the observed statistic.

**References**

Venkatraman, E.S. (2000) A permutation test to compare receiver operating characteristic curves. *Biometrics* 56(4):1134-8.

**Examples**

```
d <- rep(0:1, 50)
x <- rnorm(100) + 1.2*d
y <- rnorm(100) + 1.2*d
oo <- roc.perm.test(x, d, marker2=y)
plot(oo)
oo <- roc.perm.test(c(x,y), c(d,d), group=rep(1:2,each=100))
plot(oo)
```

---

 ROCanalysis

*Functions to plot and compare ROC curves.*

---

**Description**

These functions can be used for nonparametric analysis of ROC curves.

**Details**

The relevant functions are `roc.curve`, `roc.area.test` and `roc.perm.test`. See the individual functions for usage details.

---

 toxbdry

*Stopping rule for toxicity/futility monitoring*

---

**Description**

Computes a stopping rule and its operating characteristics for toxicity monitoring based repeated significance testing.

**Usage**

```

toxbdry(pLo, pHi, n, cP0=0.1, cP1=0.9, ngrid=6, niter=10, delta=0,
        priority=c("null", "alt"))
futilbdry(rLo, rHi, n, size=0.1, power=0.9, ngrid=3, niter=10, delta=0.5)
bdrycross.prob(n, r, ptox)
## S3 method for class 'toxbdry'
print(x, ...)
## S3 method for class 'futilbdry'
print(x, ...)

```

**Arguments**

pLo	the toxicity rate that is acceptable.
rLo	baseline (null) response rate.
pHi	the toxicity rate that is too high and hence unacceptable.
rHi	desirable response rate. Stop when it is too unlikely.
n	vector of times (sample size) when toxicity/response is monitored.
r	vector of maximum acceptable toxicities (non-responders for futility) corresponding to n.
ptox	the toxicity rates for which the operating characteristics are calculated. For futility this is the non-response rate.

cP0	boundary crossing probability under pLo i.e. type I error or the probability of declaring a treatment with toxicity rate pLo unacceptable.
cP1	boundary crossing probability under pHi i.e. power or the probability of declaring a treatment with toxicity rate pHi unacceptable.
size	probability of calling drug effective if response rate is rLo.
power	probability of calling drug effective if response rate is rHi.
ngrid	the number of toxicity rates from pLo to pHi for which the operating characteristics are computed.
niter	the number of iterations run to obtain the boundary.
delta	power determining the shape of the boundary. Should be between 0 (default) and 0.5.
priority	the error threshold to prioritize when the max sample size is too small to have both error thresholds satisfied. Default is the null i.e. error under pLo.
x	object returned by the function toxbdry.
...	additional arguments to print.

### Details

The shape parameter delta is used to determine the stopping boundary with 0 corresponding to the Pocock boundary where the same significance level is used for all looks and 0.5 corresponding to the O'Brien-Fleming boundary which has smaller probability of stopping at early looks.

Default value of delta for toxicity monitoring is 0; value between 0.1 and 0.2 is a reasonable choice to make it less likely to stop early. Default values of delta for futility stopping is 0.5.

For toxicity monitoring two sets of probabilities - pstop and pcross - are given which correspond to probability of stopping early and probability of declaring the treatment too toxic with the full complement of study subjects accrued and treated.

For futility monitoring instead two sets of probabilities - pstop and peffective - are given corresponding to the probability of stopping early for futility and probability of finishing the trial and declaring it a success. Note that peffective is the complement of pcross in toxicity monitoring.

The futility boundary can have a -1 in earlier looks which means that even zero responses is not sufficient for stopping at that look.

The exact calculations in this function are done along the lines of the method in Chapter 12 of Jennison and Turnbull (2000). Ivanova, Qaqish and Schell (2005) have an illustrative paper.

### Value

the function returns a list with:

looks	when toxicity is monitored - same as input n.
lo.bdry	lower boundary is a vector of maximum acceptable number of toxicities corresponding the number of subjects in n. The boundary crossing probability for this is slightly above cP0.
hi.bdry	upper boundary is a vector of maximum acceptable number of toxicities corresponding the number of subjects in n. The boundary crossing probability for this is slightly below cP0.

bdry.oc            the operating characteristics i.e the toxicity rate, the probability of crossing, stopping (i.e. cross before the last observation) and the expected sample size for both the low (lo) and high (hi) boundaries.

bdry.alpha        the alpha levels for testing at each look for the two boundaries.

stopping for toxicity is done when the number of toxicities exceeds the boundary i.e. the boundary gives the maximum acceptable number.

## Examples

```
toxbdry(0.2, 0.35, c(20,40,60,75))
toxbdry(0.2, 0.3, c(20,40,60,75), cP0=0.15, cP1=0.8)
# continuous monitoring
toxbdry(0.1, 0.3, 2:30)
# prioritize cP1 error threshold
toxbdry(0.1, 0.3, 2:25, priority="alt")
```

---

twostage.admissible    *Admissible design options between Minimax and Optimal*

---

## Description

Lists the admissible design options between

## Usage

```
twostage.admissible(x)
```

## Arguments

x                    output from ph2simon call

## Value

twostage.admissible returns design options that are admissible (Jung et al, 2004). The output is a matrix with 8 columns: r1, n1, r, n, EN(p0), PET(p0), qLo, qHi. The columns qLo and qHi give the range of probability values for which the particular design is admissible.

## References

Jung SH, Lee T, Kim K, and George, SL. (2004). Admissible two-stage designs for phase II cancer clinical trials. *Statistics in medicine* 23(4), 561-569.

**Examples**

```
oo = ph2simon(0.5, 0.7, 0.05, 0.1)
twostage.admissible(oo)
```

---

twostage.inference      *Inference following a two-stage design for binary response*

---

**Description**

Calculates the p-value, UMVUE and CI for the data from a study using a two stage design for response.

**Usage**

```
twostage.inference(x, r1, n1, n, pu, alpha=0.05)
```

**Arguments**

x	number of responses observed at the end of the study
r1	first stage threshold to declare treatment undesirable
n1	first stage sample size
n	total sample size
pu	unacceptable response rate (null hypothesis)
alpha	the confidence level. For consistency with the design use the same value from the design. (default is 0.05)

**Value**

twostage.inference returns the UMVUE (Jung & Kim, 2004), p-value and CI (Koyama & Chen, 2008). The CI has confidence level  $1-2*\alpha$  and the one-sided  $(1-\alpha)$  interval consistent with the design is obtained by changing the upper confidence limit (UCL) to 1.
