Title Conditional Maximum Likelihood for Quadratic Exponential Models
for Binary Panel Data

Version 2.3

Date 2023-02-27

Author Francesco Bartolucci (University of Perugia),
Claudia Pigini (University of Ancona ``Politecnica delle Marche''),
Francesco Valentini (University of Ancona ``Politecnica delle Marche'')

Maintainer Francesco Bartolucci <francesco.bartolucci@unipg.it>

Description Estimation, based on conditional maximum likelihood, of the quadratic exponential model proposed by Bartolucci, F. & Nigro, V. (2010, *Econometrica*) <[DOI:10.3982/ECTA7531](https://doi.org/10.3982/ECTA7531)> and of a simplified and a modified version of this model. The quadratic exponential model is suitable for the analysis of binary longitudinal data when state dependence (further to the effect of the covariates and a time-fixed individual intercept) has to be taken into account. Therefore, this is an alternative to the dynamic logit model having the advantage of easily allowing conditional inference in order to eliminate the individual intercepts and then getting consistent estimates of the parameters of main interest (for the covariates and the lagged response). The simplified version of this model does not distinguish, as the original model does, between the last time occasion and the previous occasions. The modified version formulates in a different way the interaction terms and it may be used to test in a easy way state dependence as shown in Bartolucci, F., Nigro, V. & Pigini, C. (2018, *Econometric Reviews*) <[DOI:10.1080/07474938.2018.1450039](https://doi.org/10.1080/07474938.2018.1450039)>.

The package also includes estimation of the dynamic logit model by a pseudo conditional estimator based on the quadratic exponential model, as proposed by Bartolucci, F. & Nigro, V. (2012, *Journal of Econometrics*) <[DOI:10.1016/j.jeconom.2012.03.004](https://doi.org/10.1016/j.jeconom.2012.03.004)>.

For large time dimensions of the panel, the computation of the proposed models involves a recursive function from Kralio M. D., & Pike M. C. (1984, *Journal of the Royal Statistical Society. Series C (Applied Statistics)*) and Bartolucci F., Valentini, F. & Pigini C. (2021, *Computational Economics*) <[DOI:10.1007/s10614-021-10218-2](https://doi.org/10.1007/s10614-021-10218-2)>.

*Conditional Maximum Likelihood for Quadratic Exponential Models
for Binary Panel Data*

Description

Estimation, based on conditional maximum likelihood, of the quadratic exponential model proposed by Bartolucci & Nigro (2010) and of a simplified and a modified version of this model. The quadratic exponential model is suitable for the analysis of binary longitudinal data when state dependence (further to the effect of the covariates and a time-fixed individual intercept) has to be taken into account. Therefore, this is an alternative to the dynamic logit model having the advantage of easily allowing conditional inference in order to eliminate the individual intercepts and then getting consistent estimates of the parameters of main interest (for the covariates and the lagged response). The simplified version of this model does not distinguish, as the original model does, between the last time occasion and the previous occasions. The modified version formulates in a different way the interaction terms and it may be used to test in a easy way state dependence as shown in Bartolucci, Nigro & Pigini (2018). The package also includes estimation of the dynamic logit model by a pseudo conditional estimator based on the quadratic exponential model, as proposed by Bartolucci & Nigro (2012).

Examples

```
# example based on simulated data
data(data_sim)
data_sim = data_sim[1:500,] # to speed up the example, remove otherwise
# static model
out1 = cquad(y~X1+X2,data_sim)
# dynamic model
out2 = cquad(y~X1+X2,data_sim,dyn=TRUE)
```

cquad*Interface for functions fitting different versions of cquad*

Description

Fit by conditional maximum likelihood each of the models in *cquad* package.

Usage

```
cquad(formula, data, index = NULL, model = c("basic", "equal", "extended", "pseudo"),
      w = rep(1, n), dyn = FALSE, Ttol=10)
```

Arguments

<code>formula</code>	formula with the same syntax as in <i>plm</i> package
<code>data</code>	<code>data.frame</code> or <code>pdata.frame</code>
<code>index</code>	to denote panel structure as in <i>plm</i> package
<code>model</code>	type of model = "basic", "equal", "extended", "pseudo"
<code>w</code>	vector of weights (optional)
<code>dyn</code>	TRUE if in the dynamic version; FALSE for the static version (by default)
<code>Ttol</code>	Threshold individual observations that activates the recursive algorithm (default=10)

Value

<code>formula</code>	formula defining the model
<code>lk</code>	conditional log-likelihood value
<code>coefficients</code>	estimate of the regression parameters
<code>vcov</code>	asymptotic variance-covariance matrix for the parameter estimates
<code>scv</code>	matrix of individual scores
<code>J</code>	Hessian of the log-likelihood function
<code>se</code>	standard errors
<code>ser</code>	robust standard errors
<code>Tv</code>	number of time occasions for each unit

Author(s)

Francesco Bartolucci (University of Perugia), Claudia Pignini (University of Ancona "Politecnica delle Marche"), Francesco Valentini (University of Ancona "Politecnica delle Marche")

Examples

```
# example based on simulated data
data(data_sim)
data_sim = data_sim[1:500,] # to speed up the example, remove otherwise
# basic (static) model
out1 = cquad(y~X1+X2,data_sim)
summary(out1)
# basic (dynamic) model
out2 = cquad(y~X1+X2,data_sim,dyn=TRUE)
summary(out2)
# equal model
out3 = cquad(y~X1+X2,data_sim,model="equal")
summary(out3)
# extended model
out4 = cquad(y~X1+X2,data_sim,model="extended")
summary(out4)
# psuedo CML for dynamic model
out5 = cquad(y~X1+X2,data_sim,model="pseudo")
summary(out5)
```

cquad_basic

Conditional maximum likelihood estimation of the basic quadratic exponential model

Description

Fit by conditional maximum likelihood a simplified version of the model for binary longitudinal data proposed by Bartolucci & Nigro (2010); see also Cox (1972).

Usage

```
cquad_basic(id, yv, X = NULL, be = NULL, w = rep(1, n), dyn =
FALSE, Ttol=10)
```

Arguments

id	list of the reference unit of each observation
yv	corresponding vector of response variables
X	corresponding matrix of covariates (optional)
be	initial vector of parameters (optional)
w	vector of weights (optional)
dyn	TRUE if in the dynamic version; FALSE for the static version (by default)
Ttol	Threshold individual observations that activates the recursive algorithm (default=10)

Value

formula	formula defining the model
lk	conditional log-likelihood value
coefficients	estimate of the regression parameters (including for the lag-response)
vcov	asymptotic variance-covariance matrix for the parameter estimates
scv	matrix of individual scores
J	Hessian of the log-likelihood function
se	standard errors
ser	robust standard errors
Tv	number of time occasions for each unit

Author(s)

Francesco Bartolucci (University of Perugia), Claudia Pignini (University of Ancona "Politecnica delle Marche"), Francesco Valentini (University of Ancona "Politecnica delle Marche")

References

- Cox, D. R. (1972), The Analysis of multivariate binary data, *Applied Statistics*, **21**, 113-120.

Examples

```
# example based on simulated data
data(data_sim)
data_sim = data_sim[1:500,] # to speed up the example, remove otherwise
id = data_sim$id; yv = data_sim$y; X = cbind(X1=data_sim$X1,X2=data_sim$X2)
# static model
out1 = cquad_basic(id,yv,X,Ttol=10)
summary(out1)
# dynamic model
out2 = cquad_basic(id,yv,X,dyn=TRUE,Ttol=10)
summary(out2)
```

Description

Fit by conditional maximum likelihood a modified version of the model for binary longitudinal data proposed by Bartolucci & Nigro (2010), in which the interaction terms have an extended form. This modified version is used to test for state dependence as described in Bartolucci et al. (2018).

Usage

```
cquad_equ(id, yv, X = NULL, be = NULL, w = rep(1, n), Ttol=10)
```

Arguments

<code>id</code>	list of the reference unit of each observation
<code>yv</code>	corresponding vector of response variables
<code>X</code>	corresponding matrix of covariates (optional)
<code>be</code>	initial vector of parameters (optional)
<code>w</code>	vector of weights (optional)
<code>Ttol</code>	Threshold individual observations that activates the recursive algorithm (default=10)

Value

<code>formula</code>	formula defining the model
<code>lk</code>	conditional log-likelihood value
<code>coefficients</code>	estimate of the regression parameters (including for the lag-response)
<code>vcov</code>	asymptotic variance-covariance matrix for the parameter estimates
<code>scv</code>	matrix of individual scores
<code>J</code>	Hessian of the log-likelihood function
<code>se</code>	standard errors
<code>ser</code>	robust standard errors
<code>Tv</code>	number of time occasions for each unit

Author(s)

Examples

```
# example based on simulated data
data(data_sim)
data_sim = data_sim[1:500,] # to speed up the example, remove otherwise
id = data_sim$id; yv = data_sim$y; X = cbind(X1=data_sim$X1,X2=data_sim$X2)

out = cquad_equ(id,yv,X,Ttol=10)
```

cquad_ext

Conditional maximum likelihood estimation of the quadratic exponential model for panel data

Description

Fit by conditional maximum likelihood the model for binary longitudinal data proposed by Bartolucci & Nigro (2010).

Usage

```
cquad_ext(id, yv, X = NULL, be = NULL, w = rep(1, n), Ttol=10)
```

Arguments

id	list of the reference unit of each observation
yv	corresponding vector of response variables
X	corresponding matrix of covariates (optional)
be	initial vector of parameters (optional)
w	vector of weights (optional)
Ttol	Threshold individual observations that activates the recursive algorithm (default=10)

Value

formula	formula defining the model
lk	conditional log-likelihood value
coefficients	estimate of the regression parameters (including for the lag-response)
vcov	asymptotic variance-covariance matrix for the parameter estimates
scv	matrix of individual scores
J	Hessian of the log-likelihood function
se	standard errors
ser	robust standard errors
Tv	number of time occasions for each unit

```
# example based on simulated data
data(data_sim)
data_sim = data_sim[1:500,] # to speed up the example, remove otherwise
id = data_sim$id; yv = data_sim$y; X = cbind(X1=data_sim$X1,X2=data_sim$X2)
# static model
out = cquad_ext(id,yv,X,Ttol=10)
summary(out)
```

cquad_pseudo

Pseudo conditional maximum likelihood estimation of the dynamic logit model

Description

Estimate the dynamic logit model for binary longitudinal data by the pseudo conditional maximum likelihood method proposed by Bartolucci & Nigro (2012).

Usage

```
cquad_pseudo(id, yv, X = NULL, be = NULL, w = rep(1,n), Ttol=10)
```

Arguments

id	list of the reference unit of each observation
yv	corresponding vector of response variables
X	corresponding matrix of covariates (optional)
be	initial vector of parameters (optional)
w	vector of weights (optional)
Ttol	Threshold individual observations that activates the recursive algorithm (default=10)

Value

formula	formula defining the model
lk	conditional log-likelihood value
coefficients	estimate of the regression parameters (including for the lag-response)
vcov	asymptotic variance-covariance matrix for the parameter estimates
scv	matrix of individual scores
J	Hessian of the log-likelihood function
se	standard errors
se2	robust standard errors that also take into account the first step
Tv	number of time occasions for each unit

Author(s)

Examples

```
## Not run:
# example based on simulated data
data(data_sim)
data_sim = data_sim[1:500,] # to speed up the example, remove otherwise
id = data_sim$id; yv = data_sim$y; X = cbind(X1=data_sim$X1,X2=data_sim$X2)
# estimate dynamic logit model
out = cquad_pseudo(id,yv,X, Ttol=10)
summary(out)

## End(Not run)
```

data_sim

Simulated dataset

Description

It contains a dataset simulated from the dynamic logit model

Usage

```
data(data_sim)
```

Format

The observations are for 1000 sample units at 5 time occasions:

id list of the reference unit of each observation
 time number of the time occasion
 X1 first covariate
 X2 second covariate
 y response

Examples

```
data(data_sim)
head(data_sim)
```

<code>print.cquad</code>	<i>Print output for class cquad</i>
--------------------------	-------------------------------------

Description

Print output for class `cquad` and output provided by `cquad_basic`, `cquad_equ`, `cquad_ext`, `cquad_pseudo`

Usage

```
## S3 method for class 'cquad'
print(x, ...)
```

Arguments

x	output of class <code>cquad</code>
...	further arguments passed to or from other methods

Author(s)

Francesco Bartolucci (University of Perugia), Claudia Pigini (University of Ancona "Politecnica delle Marche")

<code>quasi_sym</code>	<i>Recursive computation of the conditional likelihood for the Quadratic Exponential Model proposed in Bartolucci & Nigro (2010)</i>
------------------------	--

Description

Recursively compute the denominator of the individual conditional likelihood function for the Quadratic Exponential Model, adapted from Kralio & Pike (1984).

Usage

```
quasi_sym(eta, s, dyn=FALSE, y0=NULL)
```

Arguments

eta	individual vector of products between covariate and parameters
s	total score of the individual
dyn	TRUE if in the dynamic version; FALSE for the static version (by default)
y0	Individual initial observation for dynamic models

Value

f	value of the denominator
d1	first derivative of the recursive function
d11	a component of the score function
D2	second derivative of the recursive function
D12	a component of the Hessian matrix

Author(s)

Francesco Bartolucci (University of Perugia), Claudia Pignini (University of Ancona "Politecnica delle Marche"), Francesco Valentini (University of Ancona "Politecnica delle Marche")

quasi_sym_equ

Recursive computation of the conditional likelihood for the Modified Quadratic Exponential Model proposed in Bartolucci et al. (2018)

Description

Recursively compute the denominator of the individual conditional likelihood function for the Modified Quadratic Exponential Model recursively, adapted from Krailo & Pike (1984).

Usage

```
quasi_sym_equ(eta, s, y0=NULL)
```

Arguments

eta	individual vector of products between covariate and parameters
s	total score of the individual
y0	Individual initial observation for dynamic models

Value

f	value of the denominator
d1	first derivative of the recursive function
d11	a component of the score function
D2	second derivative of the recursive function
D12	a component of the Hessian matrix

Author(s)

Francesco Bartolucci (University of Perugia), Claudia Pigini (University of Ancona "Politecnica delle Marche"), Francesco Valentini (University of Ancona "Politecnica delle Marche")

quasi_sym_pseudo

Recursive computation of pseudo conditional maximum likelihood method proposed by Bartolucci & Nigro (2012).

Description

Recursively compute the denominator of the individual conditional likelihood function for the pseudo conditional maximum likelihood method proposed by Bartolucci & Nigro (2012) recursively, adapted from Krailo & Pike (1984).

Usage

```
quasi_sym_pseudo(eta, qi, s, y0=NULL)
```

Arguments

eta	individual vector of products between covariate and parameters
s	total score of the individual
qi	Vector of quantities from first step estimation
y0	Individual initial observation for dynamic models

Value

f	value of the denominator
d1	first derivative of the recursive function
d11	a component of the score function
D2	second derivative of the recursive function
D12	a component for the Hessian matrix

Author(s)

sim_panel_logit *Simulate data from the dynamic logit model*

Description

Simulate data from the dynamic logit model given a set of covariates and a vector of parameters.

Usage

```
sim_panel_logit(id, al, X = NULL, eta, dyn = FALSE)
```

Arguments

id	list of the reference unit of each observation
al	list of individual specific effects
X	corresponding matrix of covariates (optional)
eta	vector of parameters
dyn	TRUE if in the dynamic version; FALSE for the static version (by default)

Value

- yv simulated vector of binary response variables
 pv vector of probabilities of "success"

Author(s)

Francesco Bartolucci (University of Perugia), Claudia Pigini (University of Ancona "Politecnica delle Marche")

Examples

```
# simulate data from the static logit model
n = 1000; TT = 5 # sample size, number of time occasions
id = (1:n)%x%rep(1,TT) # vector of indices
al = rnorm(n) # simulate alpha
X = matrix(rnorm(2*n*TT),n*TT,2) # simulate two covariates
eta1 = c(1,-1) # vector of parameters
out = sim_panel_logit(id,al,X,eta1)
y1 = out$yv

# simulate data from the dynamic logit model
eta2 = c(1,-1,2) # vector of parameters including state dependence
out = sim_panel_logit(id,al,X,eta2,dyn=TRUE)
y2 = out$yv
```

sq

*Generate binary sequences***Description**

Generate binary sequences of a certain length and with a certain sum.

Usage

```
sq(J, s = NULL)
```

Arguments

- J length of the binary sequences
 s sum of the binary sequences (optional)

Value

- M Matrix of binary configurations

Author(s)

Francesco Bartolucci (University of Perugia)

Examples

```
# generate all sequence of 5 binary variables  
sq(5)  
# generate all sequence of 5 binary variables, with sum equal 2  
sq(5,2)
```

summary.cquad

Summary for class cquad

Description

Summarize the output for class `cquad` provided by `cquad_basic`, `cquad_equ`, `cquad_ext`, `cquad_pseudo`

Usage

```
## S3 method for class 'cquad'  
summary(object, ...)
```

Arguments

<code>object</code>	output of class <code>cquad</code>
<code>...</code>	further arguments passed to or from other methods

Author(s)

Francesco Bartolucci (University of Perugia), Claudia Pigini (University of Ancona "Politecnica delle Marche")
