# Package 'mvtnorm’ 

May 21, 2024
Title Multivariate Normal and t Distributions
Version 1.2-5
Date 2024-05-18
Description Computes multivariate normal and $t$ probabilities, quantiles, random deviates, and densities. Log-likelihoods for multivariate Gaussian models and Gaussian copulae parameterised by Cholesky factors of covariance or precision matrices are implemented for interval-censored and exact data, or a mix thereof. Score functions for these log-likelihoods are available. A class representing multiple lower triangular matrices and corresponding methods are part of this package.

mvtnorm-package Multivariate Normal and t Distributions

## Description

Computes multivariate normal and t probabilities, quantiles, random deviates, and densities. Loglikelihoods for multivariate Gaussian models and Gaussian copulae parameterised by Cholesky factors of covariance or precision matrices are implemented for interval-censored and exact data, or a mix thereof. Score functions for these log-likelihoods are available. A class representing multiple lower triangular matrices and corresponding methods are part of this package.

## Details

Package mvtnorm provides functionality for dealing with multivariate normal and t-distributions. The package interfaces FORTRAN and C code for evaluating multivariate normal probabilities written by Alan Genz and Tetsuhisa Miwa. Functions pmvnorm, pmvt, qmvnorm, and qmvt return normal and $t$ probabilities or corresponding quantiles computed by these original implementations. Users interested in the computation of such probabilities or quantiles, for example for multiple testing purposes, should use this functionality.

When the multivariate normal log-likelihood function, defined by the log-probability in the discrete or interval-censored case or by the log-density for exact real observations, or a mix thereof, shall be computed, functions lpmvnorm, ldmvnorm, and ldpmvnorm are better suited. They rely on an independent implementation of Genz' algorithm (for log-probabilities), can be customised (different quasi-Monte Carlo schemes), and are a bit faster. Most importantly, the corresponding score functions are available through functions slpmvnorm, sldmvnorm, or sldpmvnorm, which help to speed-up parameter estimation considerably. Users interested in this functionality should consult the lmvnorm_src package vignette.

```
See Also
    vignette("lmvnorm_src", package = "mvtnorm")
```

## Description

Choose between three algorithms for evaluating normal (and t-) distributions and define hyper parameters.

```
Usage
    GenzBretz(maxpts = 25000, abseps = 0.001, releps = 0)
    Miwa(steps = 128, checkCorr = TRUE, maxval = 1e3)
    TVPACK(abseps = 1e-6)
```

## Arguments

maxpts maximum number of function values as integer. The internal FORTRAN code always uses a minimum number depending on the dimension. (for example 752 for three-dimensional problems).
abseps absolute error tolerance; for TVPACK only used for dimension 3.
releps relative error tolerance as double.
steps number of grid points to be evaluated; cannot be larger than 4097.
checkCorr logical indicating if a check for singularity of the correlation matrix should be performed (once per function call to pmvt () or pmvnorm()).
maxval replacement for Inf when non-orthant probabilities involving Inf shall be computed.

## Details

There are three algorithms available for evaluating normal (and two algorithms for t -) probabilities: The default is the randomized Quasi-Monte-Carlo procedure by Genz (1992, 1993) and Genz and Bretz (2002) applicable to arbitrary covariance structures and dimensions up to 1000 .
For normal probabilities, smaller dimensions (up to 20) and non-singular covariance matrices, the algorithm by Miwa et al. (2003) can be used as well. This algorithm can compute orthant probabilities (lower being -Inf or upper equal to Inf). Non-orthant probabilities are computed from the corresponding orthant probabilities, however, infinite limits are replaced by maxval along with a warning.
For two- and three-dimensional problems and semi-infinite integration region, TVPACK implements an interface to the methods described by Genz (2004).

## Value

An object of class "GenzBretz", "Miwa", or "TVPACK" defining hyper parameters.

## lpmvnorm Multivariate Normal Log-likelihood and Score Functions

## Description

Computes the log-likelihood (contributions) of multiple exact or interval-censored observations (or a mix thereof) from multivariate normal distributions and evaluates corresponding score functions.

## Usage

lpmvnorm(lower, upper, mean $=0$, center $=$ NULL, chol, invchol, logLik $=$ TRUE,
M = NULL, w = NULL, seed = NULL, tol = .Machine\$double.eps, fast = FALSE)
slpmvnorm(lower, upper, mean $=0$, center $=$ NULL, chol, invchol, logLik $=$ TRUE,
$M=N U L L, w=N U L L$, seed $=$ NULL, tol $=$.Machine\$double.eps, fast = FALSE)
ldmvnorm(obs, mean $=0$, chol, invchol, logLik = TRUE)
sldmvnorm(obs, mean $=0$, chol, invchol, logLik $=$ TRUE)
ldpmvnorm(obs, lower, upper, mean = 0, chol, invchol, logLik = TRUE, ...)
sldpmvnorm(obs, lower, upper, mean = 0, chol, invchol, logLik = TRUE, ...)

## Arguments

lower matrix of lower limits (one column for each observation, $J$ rows).
upper matrix of upper limits (one column for each observation, $J$ rows).
obs matrix of exact observations (one column for each observation, $J$ rows).
mean matrix of means (one column for each observation, length is recycled to length of obs, lower and upper).

| center | matrix of negative rescaled means (one column for each observation, length is recycled to length of lower and upper) as returned by cond_mvnorm(..., center = TRUE). |
| :---: | :---: |
| chol | Cholesky factors of covariance matrices as ltMatrices object, length is recylced to length of obs, lower and upper. |
| invchol | Cholesky factors of precision matrices as ltMatrices object, length is recylced to length of lower and upper. Either chol or invchol must be given. |
| logLik | logical, if TRUE, the log-likelihood is returned, otherwise the individual contributions to the sum are returned. |
| M | number of iterations, early stopping based on estimated errors is NOT implemented. |
| w | an optional matrix of weights with $J-1$ rows. This allows to replace the default Monte-Carlo procedure (Genz, 1992) with a quasi-Monte-Carlo approach (Genz \& Bretz, 2002). Note that the same weights for evaluating the multivariate normal probability are used for all observations when $n \operatorname{col}(w)==M$ is specified. If ncol $(w)==n c o l$ (lower) * $M$, each likelihood contribution is evaluated on the corresponding sub-matrix. If $w$ is NULL, different uniform numbers are drawn for each observation. |
| seed | an object specifying if and how the random number generator should be initialized, see simulate. Only applied when w is NULL. |
| tol | tolerance limit, values smaller than tol are interpreted as zero. |
| fast | logical, if TRUE, a faster but less accurate version of pnorm is used internally. additional arguments to lpmvnorm. |

## Details

Evaluates the multivariate normal log-likelihood defined by means and chol over boxes defined by lower and upper or for exact observations obs.

Monte-Carlo (Genz, 1992, the default) and quasi-Monte-Carlo (Genz \& Bretz, 2002) integration is implemented, the latter with weights obtained, for example, from packages qrng or randtoolbox. It is the responsibility of the user to ensure a meaningful lattice is used. In case of doubt, use plain Monte-Carlo ( $\mathrm{w}=$ NULL) or pmvnorm.
slpmvnorm computes both the individual log-likelihood contributions and the corresponding score matrix (of dimension $J \times(J+1) / 2 \times N$ ) if chol contains diagonal elements. Otherwise, the dimension is $J \times(J-1) / 2 \times N$. The scores for exact or mixed exact-interval observations are computed by sldmvnorm and sldpmvnorm, respectively.

More details can be found in the lmvnorm_src package vignette.

## Value

The log-likelihood (logLik = TRUE) or the individual contributions to the log-likelihood. slpmvnorm, sldmvnorm, and sldpmvnorm return the score matrices and, optionally (logLik = TRUE), the individual log-likelihood contributions as well as scores for obs, lower, upper, and mean.

## Examples

```
    ### five observations
    N <- 5L
    ### dimension
    J <- 4L
    ### lower and upper bounds, ie interval-censoring
    lwr <- matrix(-runif(N * J), nrow = J)
    upr <- matrix(runif(N * J), nrow = J)
    ### Cholesky factor
    (C <- ltMatrices(runif(J * (J + 1) / 2), diag = TRUE))
    ### corresponding covariance matrix
    (S <- as.array(Tcrossprod(C))[,,1])
    ### plain Monte-Carlo (Genz, 1992)
    w <- NULL
    M <- 25000
    ### quasi-Monte-Carlo (Genz & Bretz, 2002, but with different weights)
    if (require("qrng")) w <- t(ghalton(M * N, J - 1))
    ### log-likelihood
    lpmvnorm(lower = lwr, upper = upr, chol = C, w = w, M = M)
    ### compare with pmvnorm
    exp(lpmvnorm(lower = lwr, upper = upr, chol = C, logLik = FALSE, w = w, M = M))
    sapply(1:N, function(i) pmvnorm(lower = lwr[,i], upper = upr[,i], sigma = S))
    ### log-lik contributions and score matrix
    slpmvnorm(lower = lwr, upper = upr, chol = C, w = w, M = M, logLik = TRUE)
```

    ItMatrices Multiple Lower Triangular or Symmetric Matrices
    
## Description

A class representing multiple lower triangular or symmetric matrices and some methods.

## Usage

```
ltMatrices(object, diag = FALSE, byrow = FALSE, names = TRUE)
syMatrices(object, diag = FALSE, byrow = FALSE, names = TRUE)
as.syMatrices(object)
## S3 method for class 'ltMatrices'
as.array(x, symmetric = FALSE, ...)

## S3 method for class 'ltMatrices'
aperm(a, perm, is_chol = FALSE, ...)
## S3 method for class 'ltMatrices'
Mult(x, y, transpose = FALSE, ...)
## S3 method for class 'syMatrices'
Mult(x, y, ...)
Tcrossprod(x, diag_only = FALSE)
Crossprod(x, diag_only = FALSE)
Lower_tri(x, diag = FALSE, byrow = attr(x, "byrow"))
chol2cov(x)
invchol2chol(x)
chol2invchol(x)
invchol2cov(x)
invchol2pre(x)
chol2pre(x)
Dchol(x, D = 1 / sqrt(Tcrossprod(x, diag_only = TRUE)))
invcholD(x, D = sqrt(Tcrossprod(solve(x), diag_only = TRUE)))
chol2cor(x)
invchol2cor(x)
chol2pc(x)
invchol2pc(x)
vectrick(C, S, A, transpose = c(TRUE, TRUE))
standardize(chol, invchol)
```

```
destandardize(chol = solve(invchol), invchol, score_schol)
```

## Arguments

| object | a matrix representing the lower triagular elements of $N$ lower triangular matrix, each of dimension $J \times J$. Dimensions of object depend on diag: With diagonal elements, object is a $J(J+1) / 2 \times N$ matrix, otherwise, the number of rows is $J(J-1) / 2$. |
| :---: | :---: |
| diag | logical, object contains diagonal elements if TRUE, otherwise unit diagonal elements are assumed. |
| byrow | logical, object represents matrices in row-major order if TRUE or, otherwise, in column-major order. |
| names | logical or character vector of length $J$. |
| symmetric | logical, object is interpreted as a symmetric matrix if TRUE. |
| diag_only | logical, compute diagonal elements of crossproduct only if TRUE. |
| x, chol, invchol | object of class ltMatrices or syMatrices (for chol). |
| value | a matrix of diagonal elements to be assigned (of dimension $J \times N$ ). |
| a | object of class ltMatrices. |
| perm | a permutation of the covariance matrix corresponding to a. |
| is_chol | a logical indicating if $a$ is the Cholesky of the covariance (chol = TRUE) of the precision matrix. |
| D | a matrix (of dimension $J \times N$ ) of diagonal elements to be multiplied with. |
| y | matrix with $J$ rows. |
| b | matrix with $J$ rows. |
| C | an object of class ltMatrices. |
| S | an object of class ltMatrices or a matrix with $J^{2}$ rows representing multiple $J x J$ matrices (columns of vec operators). |
| A | an object of class ltMatrices. |
| transpose | a logical of length two indicating if $A$ or $B$ shall be transposed in vectrick. For solve, this argument being true computes solve $(t(a), b)$ (in absence of at () method for ltMatrices objects). |
| score_schol | score matrix for a standardized chol object. |
|  | additional arguments, currently ignored. |

## Details

ltMatrices interprets a matrix as lower triangular elements of multiple lower triangular matrices. The corresponding class can be used to store such matrices efficiently. Matrix multiplications, solutions to linear systems, explicite inverses, and crossproducts can be computed based on such objects. Details can be found in the lmvnorm_src package vignette.
syMatrices only store the lower triangular parts of multiple symmetric matrices.

## Value

The constructor ltMatrices returns objects of class ltMatrices with corresponding methods. The constructor syMatrices returns objects of class syMatrices with a reduced set of methods.

## Examples

```
    J <- 4L
    N <- 2L
    dm <- paste0("d", 1:J)
    xm <- paste0("x", 1:N)
    (C <- ltMatrices(matrix(runif(N * J * (J + 1) / 2),
                            ncol = N, dimnames = list(NULL, xm)),
        diag = TRUE, names = dm))
    ## dimensions and names
    dim(C)
    dimnames(C)
    names(C)
    ## subset
    C[,2:3]
    ## multiplication
    y <- matrix(runif(N * J), nrow = J)
    Mult(C, y)
    ## solve
    solve(C)
    solve(C, y)
    ## tcrossprod
    Tcrossprod(C)
    ## convert to matrix
    as.array(solve(C[1,]))[,,1]
```

margcond

## Description

Computes means and Cholesky factors of covariance or precision matrices of multiple multivariate normal distributions.

## Usage

marg_mvnorm(chol, invchol, which = 1L)
cond_mvnorm(chol, invchol, which_given = 1L, given, center = FALSE)

## Arguments

chol Cholesky factors of covariance matrices as ltMatrices object, length is recylced to length of lower and upper.
invchol Cholesky factors of precision matrices as ltMatrices object, length is recylced to length of lower and upper. Either chol or invchol must be given.
which names or indices of elements those marginal distribution is of interest.
which_given names or indices of elements to condition on.
given matrix of realisations to condition on (number of rows is equal to length(which), the number of columns corresponds to the number of matrices in chol or invchol.
center logical, if TRUE, the negative rescaled conditional mean is returned (such that it can be specified as center argument to slpmvnorm). By default, the conditional mean is returned.

## Details

Derives parameters of the requested marginal or conditional distributions, defined by chol (Cholesky factor of covariance) or invchol (Cholesky factor of precision matrix) and, for conditional distributions, the mean.
More details can be found in the lmvnorm_src package vignette.

## Value

A named list.

```

    vignette("lmvnorm_src", package = "mvtnorm")
```

Mvnorm Multivariate Normal Density and Random Deviates

## Description

These functions provide the density function and a random number generator for the multivariate normal distribution with mean equal to mean and covariance matrix sigma.

## Usage

```
dmvnorm(x, mean = rep(0, p), sigma = diag(p), log = FALSE, checkSymmetry = TRUE)
rmvnorm(n, mean = rep(0, nrow(sigma)), sigma = diag(length(mean)),
    method=c("eigen", "svd", "chol"), pre0.9_9994 = FALSE,
    checkSymmetry = TRUE, rnorm = stats::rnorm)
```

## Arguments

X
n
mean mean vector, default is rep ( 0 , length $=n \operatorname{col}(x))$. In ldmvnorm or sldmvnorm, mean is a matrix with observation-specific means arranged in columns.
sigma covariance matrix, default is diag $(n \operatorname{col}(x))$.
$\log \quad \operatorname{logical}$; if TRUE, densities $d$ are given as $\log (d)$.
method
pre0.9_9994 logical; if FALSE, the output produced in mvtnorm versions up to 0.9-9993 is
string specifying the matrix decomposition used to determine the matrix root of sigma. Possible methods are eigenvalue decomposition ("eigen", default), singular value decomposition ("svd"), and Cholesky decomposition ("chol"). The Cholesky is typically fastest, not by much though. reproduced. In 0.9-9994, the output is organized such that rmvnorm $(10, \ldots)$ has the same first ten rows as rmvnorm $(100, \ldots)$ when called with the same seed.
checkSymmetry logical; if FALSE, skip checking whether the covariance matrix is symmetric or not. This will speed up the computation but may cause unexpected outputs when ill-behaved sigma is provided. The default value is TRUE.
rnorm a function with the same interface as rnorm. This allows switching to other generators of standard normal variables.

## Details

dmvnorm computes the density function of the multivariate normal specified by mean and the covariance matrix sigma.
rmvnorm generates multivariate normal variables.

## See Also

pmvnorm, rnorm, qmvnorm, vignette("lmvnorm_src", package = "mvtnorm")

## Examples

```
dmvnorm(x=c(0,0))
dmvnorm(x=c(0,0), mean=c(1,1))
sigma <- matrix(c(4,2,2,3), ncol=2)
x <- rmvnorm(n=500, mean=c(1,2), sigma=sigma)
colMeans(x)
var(x)
dS <- dmvnorm(x, sigma = sigma)
### alternative interface
C <- t(chol(sigma))
(C <- ltMatrices(C[lower.tri(C, diag = TRUE)], diag = TRUE))
dC <- exp(ldmvnorm(obs = t(x), chol = C, logLik = FALSE))
```

```
all.equal(dS, dC)
x <- rmvnorm(n=500, mean=c(1,2), sigma=sigma, method="chol")
colMeans(x)
var(x)
plot(x)
```

## Description

These functions provide information about the multivariate $t$ distribution with non-centrality parameter (or mode) delta, scale matrix sigma and degrees of freedom df. dmvt gives the density and rmvt generates random deviates.

## Usage

```
    rmvt(n, sigma = diag(2), df = 1, delta = rep(0, nrow(sigma)),
        type = c("shifted", "Kshirsagar"), ...)
    dmvt(x, delta = rep(0, p), sigma = diag(p), df = 1, log = TRUE,
        type = "shifted", checkSymmetry = TRUE)
```

## Arguments

x
n
delta
sigma
df
log
type
vector or matrix of quantiles. If $x$ is a matrix, each row is taken to be a quantile. number of observations.
the vector of noncentrality parameters of length $n$, for type = "shifted" delta specifies the mode.
scale matrix, defaults to diag $(n \operatorname{col}(x))$.
degrees of freedom. $\mathrm{df}=0$ or $\mathrm{df}=\mathrm{Inf}$ corresponds to the multivariate normal distribution.
logical indicating whether densities $d$ are given as $\log (d)$.
type of the noncentral multivariate $t$ distribution. type = "Kshirsagar" corresponds to formula (1.4) in Genz and Bretz (2009) (see also Chapter 5.1 in Kotz and Nadarajah (2004)). This is the noncentral t-distribution needed for calculating the power of multiple contrast tests under a normality assumption. type $=$ "shifted" corresponds to the formula right before formula (1.4) in Genz and Bretz (2009) (see also formula (1.1) in Kotz and Nadarajah (2004)). It is a location shifted version of the central t-distribution. This noncentral multivariate $t$ distribution appears for example as the Bayesian posterior distribution for the regression coefficients in a linear regression. In the central case both types coincide. Note that the defaults differ from the default in pmvt() (for reasons of backward compatibility).
checkSymmetry logical; if FALSE, skip checking whether the covariance matrix is symmetric or not. This will speed up the computation but may cause unexpected outputs when ill-behaved sigma is provided. The default value is TRUE.
... additional arguments to rmvnorm(), for example method.

## Details

If $\boldsymbol{X}$ denotes a random vector following a $t$ distribution with location vector $\mathbf{0}$ and scale matrix $\Sigma$ (written $X \sim t_{\nu}(\mathbf{0}, \Sigma)$ ), the scale matrix (the argument sigma) is not equal to the covariance matrix $\operatorname{Cov}(\boldsymbol{X})$ of $\boldsymbol{X}$. If the degrees of freedom $\nu$ (the argument df) is larger than 2, then $\operatorname{Cov}(\boldsymbol{X})=$ $\Sigma \nu /(\nu-2)$. Furthermore, in this case the correlation matrix $\operatorname{Cor}(\boldsymbol{X})$ equals the correlation matrix corresponding to the scale matrix $\Sigma$ (which can be computed with cov2cor ()). Note that the scale matrix is sometimes referred to as "dispersion matrix"; see McNeil, Frey, Embrechts (2005, p. 74).

For type = "shifted" the density

$$
c\left(1+(x-\delta)^{\prime} S^{-1}(x-\delta) / \nu\right)^{-(\nu+m) / 2}
$$

is implemented, where

$$
c=\Gamma((\nu+m) / 2) /\left((\pi \nu)^{m / 2} \Gamma(\nu / 2)|S|^{1 / 2}\right),
$$

$S$ is a positive definite symmetric matrix (the matrix sigma above), $\delta$ is the non-centrality vector and $\nu$ are the degrees of freedom.
$\mathrm{df}=0$ historically leads to the multivariate normal distribution. From a mathematical point of view, rather $\mathrm{df}=\mathrm{Inf}$ corresponds to the multivariate normal distribution. This is (now) also allowed for rmvt() and dmvt().
Note that dmvt () has default log = TRUE, whereas dmvnorm() has default log = FALSE.

set.seed(271)
x. <- rmvnorm(n, mean=mu, sigma=Sigma)
stopifnot(identical(x, x.))
```

pmvnorm Multivariate Normal Distribution

## Description

Computes the distribution function of the multivariate normal distribution for arbitrary limits and correlation matrices.

## Usage

pmvnorm(lower=-Inf, upper=Inf, mean=rep(0, length(lower)), corr=NULL, sigma=NULL, algorithm = GenzBretz(), keepAttr=TRUE, seed $=$ NULL, ...)

## Arguments

lower the vector of lower limits of length $n$.
upper the vector of upper limits of length $n$.
mean the mean vector of length $n$.
corr the correlation matrix of dimension $n$.
sigma the covariance matrix of dimension $n$ less than 1000. Either corr or sigma can be specified. If sigma is given, the problem is standardized internally. If corr is given, it is assumed that appropriate standardization was performed by the user. If neither corr nor sigma is given, the identity matrix is used for sigma.

| algorithm | an object of class GenzBretz, Miwa or TVPACK specifying both the algorithm to <br> be used as well as the associated hyper parameters. |
| :--- | :--- |
| keepAttr | logical indicating if attributes such as error and msg should be attached to <br> the return value. The default, TRUE is back compatible. |
| seed | an object specifying if and how the random number generator should be initial- <br> ized, see simulate. |
| $\ldots$ | additional parameters (currently given to GenzBretz for backward compatibility <br> issues). |

## Details

This program involves the computation of multivariate normal probabilities with arbitrary correlation matrices. It involves both the computation of singular and nonsingular probabilities. The implemented methodology is described in Genz $(1992,1993)$ (for algorithm GenzBretz), in Miwa et al. (2003) for algorithm Miwa (useful up to dimension 20) and Genz (2004) for the TVPACK algorithm (which covers 2- and 3-dimensional problems for semi-infinite integration regions).
Note the default algorithm GenzBretz is randomized and hence slightly depends on .Random. seed and that both -Inf and +Inf may be specified in lower and upper. For more details see pmvt.
The multivariate normal case is treated as a special case of pmvt with $d f=0$ and univariate problems are passed to pnorm.
The multivariate normal density and random deviates are available using dmvnorm and rmvnorm.
pmvnorm is based on original implementations by Alan Genz, Frank Bretz, and Tetsuhisa Miwa developed for computing accurate approximations to the normal integral. Users interested in computing log-likelihoods involving such normal probabilities should consider function lpmvnorm, which is more flexible and efficient for this task and comes with the ability to evaluate score functions.

## Value

The evaluated distribution function is returned, if keepAttr is true, with attributes

| error | estimated absolute error |
| :--- | :--- |
| msg | status message(s). |
| algorithm | a character string with class(algorithm). |

```

pmvt Multivariate $t$ Distribution

## Description

Computes the the distribution function of the multivariate $t$ distribution for arbitrary limits, degrees of freedom and correlation matrices based on algorithms by Genz and Bretz.

## Usage

```
pmvt(lower=-Inf, upper=Inf, delta=rep(0, length(lower)),
        df=1, corr=NULL, sigma=NULL, algorithm = GenzBretz(),
        type = c("Kshirsagar", "shifted"), keepAttr=TRUE, seed = NULL, ...)
```

## Arguments

lower
upper

delta $\quad$| the vector of lower limits of length $n$. |
| :--- |
| the vector of upper limits of length $n$. |
| the vector of noncentrality parameters of length n , for type = "shifted" delta |
| specifies the mode. |
| degree of freedom as integer. Normal probabilities are computed for df=0. |
| corr |
| sigma |
| the correlation matrix of dimension n. |
| the scale matrix of dimension n . Either corr or sigma can be specified. If sigma |
| is given, the problem is standardized internally. If corr is given, it is assumed |
| that appropriate standardization was performed by the user. If neither corr nor |
| sigma is given, the identity matrix is used for sigma. |
| an object of class GenzBretz or TVPACK defining the hyper parameters of this |
| algorithm. |
| type of the noncentral multivariate t distribution to be computed. The choice |
| type = "Kshirsagar" corresponds to formula (1.4) in Genz and Bretz (2009) |
| (see also Chapter 5.1 in Kotz and Nadarajah (2004)). This is the noncentral t- |
| distribution needed for calculating the power of multiple contrast tests under a |
| normality assumption. type = "shifted" corresponds to the formula right be- |
| fore formula (1.4) in Genz and Bretz (2009) (see also formula (1.1) in Kotz and |
| Nadarajah (2004)). It is a location shifted version of the central t-distribution. |
| This noncentral multivariate t distribution appears for example as the Bayesian |
| posterior distribution for the regression coefficients in a linear regression. In the |
| central case both types coincide. |

## Details

This function involves the computation of central and noncentral multivariate $t$-probabilities with arbitrary correlation matrices. It involves both the computation of singular and nonsingular probabilities. The methodology (for default algorithm $=\operatorname{GenzBretz}()$ ) is based on randomized quasi Monte Carlo methods and described in Genz and Bretz (1999, 2002).
Because of the randomization, the result for this algorithm (slightly) depends on .Random. seed.
For 2- and 3-dimensional problems one can also use the TVPACK routines described by Genz (2004), which only handles semi-infinite integration regions (and for type = "Kshirsagar" only central problems).

For type = "Kshirsagar" and a given correlation matrix corr, for short $A$, say, (which has to be positive semi-definite) and degrees of freedom $\nu$ the following values are numerically evaluated

$$
I=2^{1-\nu / 2} / \Gamma(\nu / 2) \int_{0}^{\infty} s^{\nu-1} \exp \left(-s^{2} / 2\right) \Phi(s \cdot \text { lower } / \sqrt{\nu}-\delta, s \cdot \text { upper } / \sqrt{\nu}-\delta) d s
$$

where

$$
\Phi(a, b)=\left(\operatorname{det}(A)(2 \pi)^{m}\right)^{-1 / 2} \int_{a}^{b} \exp \left(-x^{\prime} A x / 2\right) d x
$$

is the multivariate normal distribution and $m$ is the number of rows of $A$.
For type = "shifted", a positive definite symmetric matrix $S$ (which might be the correlation or the scale matrix), mode (vector) $\delta$ and degrees of freedom $\nu$ the following integral is evaluated:

$$
c \int_{\text {lower }_{1}}^{\text {upper }_{1}} \ldots \int_{\text {lower }_{m}}^{\text {upper }_{m}}\left(1+(x-\delta)^{\prime} S^{-1}(x-\delta) / \nu\right)^{-(\nu+m) / 2} d x_{1} \ldots d x_{m},
$$

where

$$
c=\Gamma((\nu+m) / 2) /\left((\pi \nu)^{m / 2} \Gamma(\nu / 2)|S|^{1 / 2}\right),
$$

and $m$ is the number of rows of $S$.
Note that both -Inf and +Inf may be specified in the lower and upper integral limits in order to compute one-sided probabilities.

Univariate problems are passed to pt . If $\mathrm{df}=0$, normal probabilities are returned.

## Value

The evaluated distribution function is returned, if keepAttr is true, with attributes

| error | estimated absolute error and |
| :--- | :--- |
| msg | status message (a character string). |
| algorithm | a character string with class(algorithm). |

```

## Description

Computes the equicoordinate quantile function of the multivariate normal distribution for arbitrary correlation matrices based on inversion of pmvnorm, using a stochastic root finding algorithm described in Bornkamp (2018).

## Usage

```
qmvnorm(p, interval = NULL, tail = c("lower.tail", "upper.tail", "both.tails"),
    mean = 0, corr = NULL, sigma = NULL, algorithm = GenzBretz(),
    ptol = 0.001, maxiter = 500, trace = FALSE, seed = NULL, ...)
```

## Arguments

p
probability.
interval optional, a vector containing the end-points of the interval to be searched. Does not need to contain the true quantile, just used as starting values by the rootfinder. If equal to NULL a guess is used.
tail specifies which quantiles should be computed. lower.tail gives the quantile $x$ for which $P[X \leq x]=p$, upper. tail gives $x$ with $P[X>x]=p$ and both. tails leads to $x$ with $P[-x \leq X \leq x]=p$.
mean the mean vector of length $n$.
corr the correlation matrix of dimension $n$.
sigma the covariance matrix of dimension n. Either corr or sigma can be specified. If sigma is given, the problem is standardized internally. If corr is given, it is assumed that appropriate standardization was performed by the user. If neither corr nor sigma is given, the identity matrix is used for sigma.
algorithm an object of class GenzBretz, Miwa or TVPACK specifying both the algorithm to be used as well as the associated hyper parameters.
ptol, maxiter, trace
Parameters passed to the stochastic root-finding algorithm. Iteration stops when the $95 \%$ confidence interval for the predicted quantile is inside [ $p-p t o l, p+p t o l]$. maxiter is the maximum number of iterations for the root finding algorithm. trace prints the iterations of the root finder.
seed an object specifying if and how the random number generator should be initialized, see simulate.
... additional parameters to be passed to GenzBretz.

## Details

Only equicoordinate quantiles are computed, i.e., the quantiles in each dimension coincide. The result is seed dependend.

## Value

A list with two components: quantile and f.quantile give the location of the quantile and the difference between the distribution function evaluated at the quantile and $p$.

qmvt Quantiles of the Multivariate t Distribution
```

## Description

Computes the equicoordinate quantile function of the multivariate $t$ distribution for arbitrary correlation matrices based on inversion of pmvt, using a stochastic root finding algorithm described in Bornkamp (2018).

## Usage

qmvt(p, interval = NULL, tail = c("lower.tail", "upper.tail", "both.tails"), df = 1, delta = 0, corr = NULL, sigma = NULL, algorithm = GenzBretz(), type = c("Kshirsagar", "shifted"), ptol = 0.001, maxiter = 500, trace $=$ FALSE, seed $=$ NULL, ...)

## Arguments

p
interval optional, a vector containing the end-points of the interval to be searched. Does not need to contain the true quantile, just used as starting values by the rootfinder. If equal to NULL a guess is used.
tail specifies which quantiles should be computed. lower.tail gives the quantile $x$ for which $P[X \leq x]=p$, upper. tail gives $x$ with $P[X>x]=p$ and both. tails leads to $x$ with $P[-x \leq X \leq x]=p$.
delta the vector of noncentrality parameters of length $n$, for type = "shifted" delta specifies the mode.
df degree of freedom as integer. Normal quantiles are computed for $\mathrm{df}=0$ or $\mathrm{df}=$ Inf.
corr the correlation matrix of dimension n .
sigma the covariance matrix of dimension n. Either corr or sigma can be specified. If sigma is given, the problem is standardized internally. If corr is given, it is assumed that appropriate standardization was performed by the user. If neither corr nor sigma is given, the identity matrix in the univariate case (so corr = 1) is used for corr.
algorithm an object of class GenzBretz or TVPACK defining the hyper parameters of this algorithm.
type type of the noncentral multivariate $t$ distribution to be computed. The choice type = "Kshirsagar" corresponds to formula (1.4) in Genz and Bretz (2009) (see also Chapter 5.1 in Kotz and Nadarajah (2004)) and type = "shifted" corresponds to the formula before formula (1.4) in Genz and Bretz (2009) (see also formula (1.1) in Kotz and Nadarajah (2004)).
ptol, maxiter, trace
Parameters passed to the stochastic root-finding algorithm. Iteration stops when the $95 \%$ confidence interval for the predicted quantile is inside [p-ptol, $p+p t o l]$. maxiter is the maximum number of iterations for the root finding algorithm. trace prints the iterations of the root finder.
seed an object specifying if and how the random number generator should be initialized, see simulate.
... additional parameters to be passed to GenzBretz.
