

# Package ‘xmlrpc2’

May 2, 2025

**Type** Package

**Title** Implementation of the Remote Procedure Call Protocol ('XML-RPC')

**Version** 1.2

**Description** The 'XML-RPC' is a remote procedure call protocol based on 'XML'. The 'xmlrpc2' package is inspired by the 'XMLRPC' package but uses the 'curl' and 'xml2' packages instead 'RCurl' and 'XML'.

**License** GPL-3

**Imports** curl, xml2, base64enc

**Encoding** UTF-8

**NeedsCompilation** no

**Author** Florian Schwendinger [aut, cre]

**Maintainer** Florian Schwendinger <FlorianSchwendinger@gmx.at>

**Repository** CRAN

**Date/Publication** 2025-05-02 20:10:02 UTC

---

from\_xmlrpc *Convert from the XML-RPC Format into an R Object.*

---

## Description

Convert an object of class "xml\_code" or a character in the XML-RPC Format into an R Object.

**Usage**

```
from_xmlrpc(xml, raise_error = TRUE)
```

**Arguments**

<code>xml</code>	a character string containing XML in the remote procedure call protocol format.
<code>raise_error</code>	a logical controlling the behavior if the XML-RPC signals a fault. If TRUE an error is raised, if FALSE an object inheriting from "c("xmlrpc_error", "error")" is returned.

**Value**

an R object derived from the input.

**Examples**

```
params <- list(1L, 1:3, rnorm(3), LETTERS[1:3], charToRaw("A"))
xml <- to_xmlrpc("some_method", params)
from_xmlrpc(xml)
```

**rpc\_serialize**

*Convert R Objects into the XML-RPC Format*

**Description**

Serialize R Objects so they can be passed to `to_xmlrpc` as parameters.

**Usage**

```
rpc_serialize(x, ...)
```

**Arguments**

<code>x</code>	an R object.
<code>...</code>	additional optional arguments (currently ignored).

**Value**

an object of class "xml\_node".

**Examples**

```
rpc_serialize(1L)
rpc_serialize(1:2)
rpc_serialize(LETTERS[1:2])
```

---

`to_xmlrpc`*Create a XML-RPC Call*

---

## Description

Constructs the XML body for an XML-RPC request. This function takes the target method name and a list of R objects as parameters. Each parameter in the list is converted into its corresponding XML-RPC representation using the ‘`rpc_serialize`’ method. The resulting XML structure follows the XML-RPC specification for a method call, encapsulating the method name and the serialized parameters. This function is typically used internally by the main ‘`xmlrpc`’ function to prepare the request before sending it to the server, but it can also be used directly to inspect the XML that would be generated.

## Usage

```
to_xmlrpc(method, params)
```

## Arguments

- |                     |  |
|---------------------|--|
| <code>method</code> | a character string giving the name of the method to be invoked.                                      |
| <code>params</code> | a list containing the parameters which are added to the XML file sent via the remote procedure call. |

## Value

an object of class “`xml_node`” containing a XML-RPC call.

## Examples

```
params <- list(1L, 1:3, rnorm(3), LETTERS[1:3], charToRaw("A"))
cat(as.character(to_xmlrpc("some_method", params)))
```

---

`xmlrpc`*Call the Remote Procedure*

---

## Description

Call a remote procedure with the XML-RPC protocol.

## Usage

```
xmlrpc(
  url,
  method,
  params = list(),
  handle = NULL,
  opts = list(),
  convert = TRUE,
  useragent = "xmlrpc",
  raise_error = TRUE
)
```

## Arguments

url	a character string giving the url to the server.
method	a character string giving the name of the method to be invoked.
params	a list containing the parameters which are added to the XML file sent via the remote procedure call.
handle	a object of class "curl_handle".
opts	a list of options passed to the function "handle_setopt".
convert	a logical, if convert is TRUE (default) the curl response is converted else it is left unchanged.
useragent	a character string giving the name of the "User-Agent".
raise_error	a logical controlling the behavior if the status code of curl_fetch_memory signals an error. If raise_error is TRUE an error is raised, if raise_error is FALSE no error is raised and an object inheriting from c("fetch_error", "error") is returned. This object is the return value from \code{curl_fetch_memory} where just the class \code{c("fetch_error", "error")} is added.

## Value

the response of curl or the response converted to R objects.

## Examples

```
## Not run:
url <- "https://www.neos-server.org"
xmlrpc(url, "listAllSolvers")
xmlrpc(url, "listSolversInCategory", params = list(category = "socp"))

## End(Not run)
```
