Package 'PMwR'

October 19, 2025

```
Type Package
Title Portfolio Management with R
Version 1.1-0
Date 2025-10-19
Maintainer Enrico Schumann <es@enricoschumann.net>
Description Tools for the practical management of financial
     portfolios: backtesting investment and trading strategies,
     computing profit/loss and returns, analysing trades,
     handling lists of transactions, reporting, and more. The
     package provides a small set of reliable, efficient and
     convenient tools for processing and analysing
     trade/portfolio data. The manual provides all the details;
     it is available from
     <https://enricoschumann.net/R/packages/PMwR/manual/PMwR.html>.
     Examples and descriptions of new features are provided at
     <https://enricoschumann.net/notes/PMwR/>.
Imports NMOF, datetimeutils, fastmatch, orgutils, parallel, textutils,
     utils, zoo
Suggests crayon, rbenchmark, tinytest
Depends R (>= 3.5)
License GPL-3
LazyLoad yes
LazyData yes
ByteCompile yes

Description

Tools for the practical management of financial portfolios: backtesting investment and trading strategies, computing profit-and-loss and returns, analysing trades, reporting, and more.

Details

PMwR provides a small set of reliable, efficient and convenient tools for processing and analysing trade/portfolio data. The Manual provides all the details; it is available from https://enricoschumann.net/PMwR/. Examples and descriptions of new features are provided at https://enricoschumann.net/notes/PMwR/.

Adjust-Series 3

Author(s)

Enrico Schumann <es@enricoschumann.net>

References

Adjust-Series

Adjust Time Series for Dividends and Splits

Description

Adjust a time series for dividends and splits.

Usage

```
div_adjust(x, t, div, backward = TRUE, additive = FALSE)
split_adjust(x, t, ratio, backward = TRUE)
```

Arguments

X	a numeric vector: the series to be adjusted
t	An integer vector, specifying the positions in x at which dividends were paid ('ex-days') or at which a split occurred. Timestamps may be duplicated, e.g. several payments may occur on a single timestamp.
div	A numeric vector, specifying the dividends (or payments, cashflows). If necessary, recycled to the length of t.
ratio	a numeric vector, specifying the split ratios. The ratio must be 'American Style': a 2-for-1 stock split, for example, corresponds to a ratio of 2. (In other countries, for instance Germany, a 2-for-1 stock split would be called a 1-for-1 split: you keep your shares and receive one new share per share that you own.)
backward	logical; see Details
additive	logical; see Details

4 Adjust-Series

Details

The function transforms x into returns. The return in t is calculated as

$$\frac{x_t + D_t}{x_{t-1}} - 1,$$

in which x is the price, D are dividends and t is time. The adjusted x is then reconstructed from those returns.

When additive is TRUE, dividends are simply added back to the series; see Examples.

With backward set to TRUE, which is the default, the final prices in the unadjusted series matches the final prices in the adjusted series.

Value

a numeric vector of length equal to length(x)

Author(s)

Enrico Schumann

Schumann, E. (2025) *Portfolio Management with R*. https://enricoschumann.net/PMwR/ Using div_adjust for handling generic external cashflows: https://enricoschumann.net/R/packages/PMwR/manual/PMwR.html#returns-with-external-cashflows

```
x <- c(9.777, 10.04, 9.207, 9.406)
div <- 0.7
t <- 3

div_adjust(x, t, div)
div_adjust(x, t, div, FALSE)

## assume there were three splits: adjust shares outstanding shares <- c(100, 100, 200, 200, 1000, 1500)
t <- c(3, 5, 6)
ratio <- c(2, 5, 1.5)
### => invert ratio
split_adjust(shares, t, 1/ratio)
## [1] 1500 1500 1500 1500 1500

split_adjust(shares, t, 1/ratio, backward = FALSE)
## [1] 100 100 100 100 100 100
```

```
## 'additive' ** FALSE ** (default setting)
x <- c(100, 95, 100, 95, 100)
div <- 5
t <- c(2, 4)
div_adjust(x, t, div)
## 90.25 90.25 95.00 95.00 100.00
returns(div_adjust(x, t, div))
## 0.00000000 0.05263158 0.00000000 0.05263158
## ==> reflect _actual_ returns 100/95 - 1

## 'additive' ** TRUE **
div_adjust(x, t, div, additive = TRUE)
## 90 90 95 95 100
returns(div_adjust(x, t, div, additive = TRUE))
## 0.00000000 0.055555556 0.000000000 0.05263158
## ==> reflect return 95/90 - 1
```

btest

Backtesting Investment Strategies

Description

Testing trading and investment strategies.

Usage

```
btest(prices, signal,
    do.signal = TRUE, do.rebalance = TRUE,
    print.info = NULL, b = 1, fraction = 1,
    initial.position = 0, initial.cash = 0,
    final.position = FALSE,
    cashflow = NULL, tc = 0, ...,
    add = FALSE, lag = 1, convert.weights = FALSE,
    trade.at.open = TRUE, tol = 1e-5, tol.p = NA,
    Globals = list(),
    prices0 = NULL,
    include.data = FALSE, include.timestamp = TRUE,
    timestamp, instrument,
    progressBar = FALSE,
    variations, variations.settings, replications)
```

Arguments

prices

For a single asset, a matrix of prices with four columns: open, high, low and close. For n assets, a list of length four: prices[[1]] is then a matrix with n columns containing the open prices for the assets; prices[[2]] is a matrix with the high prices, and so on. If only close prices are used, then for a single asset either a matrix of one column or a numeric vector; for multiple assets a list of

length one, containing the matrix of close prices. For example, with 100 close prices of 5 assets, the prices should be arranged in a matrix p of size 100 times 5; and prices = list(p).

The series in prices are used both as transaction prices and for valuing open positions. If signals are to be based on other series, such other series should be passed via the ... argument.

Prices must be ordered by time (though the timestamps need not be provided).

signal

A function that evaluates to the position in units of the instruments suggested by the trading rule. If convert.weights is TRUE, signal should return the suggested position as weights (which need not sum to 1). If signal returns NULL, the current position is kept. See Details.

do.signal

Logical or numeric vector, a function that evaluates to TRUE or FALSE, or a string. When a logical vector, its length must match the number of observations in prices: do.signal then corresponds to the rows in prices at which a signal is computed. Alternatively, these rows may also be specified as integers. If a length-one TRUE or FALSE, the value is recycled to match the number of observations in prices. Default is TRUE: a signal is then computed in every period.

do.signal may also be the string "firstofmonth", "lastofmonth", "firstofquarter" or "lastofquarter"; in these cases, timestamp needs to specified and must be coercable to Date.

If timestamp is specified, do.signal may also be a vector of the same class as timestamp (typically Date or POSIXct). If the timestamps specified in do.signal do not occur in timestamp, a signal is computed on the next possible time instance.

do.rebalance

Same as do.signal, but it may return a logical vector of length equal to the number of assets, which indicates which assets to rebalance. Can also be the string "do.signal", in which case the value of do.signal is copied. do.rebalance is called after signal computation, so it can access the suggested position of the current period (via SuggestedPortfolio(0).

print.info

A function, called at the very end of each period, i.e. after rebalancing. Can also be NULL, in which case nothing is printed.

cashflow

A function or NULL (default).

h

burn-in (an integer). Defaults to 1. This may also be a length-one timestamp of the same class as timestamp, in which case the data up to (and including) b are skipped.

fraction

amount of rebalancing to be done: a scalar between 0 and 1

initial.position

a numeric vector: initial portfolio in units of instruments. If supplied, this will also be the initial suggested position.

initial.cash

a numeric vector of length 1. Defaults to 0.

final.position logical

tc

transaction costs as a fraction of turnover (e.g., 0.001 means 0.1%). May also be a function that evaluates to such a fraction. More-complex computations may be specified with argument cashflow.

... other named arguments. All functions (signal, do.signal, do.rebalance, print.info,

cashflow) will have access to these arguments. See Details for reserved argu-

ment names.

add Default is FALSE. TRUE is **not implemented** – but would mean that signal

should evaluate to *changes* in position, i.e. orders.

lag default is 1

convert.weights

Default is FALSE. If TRUE, the value of signal will be considered a weight vector

and automatically translated into (fractional) position sizes.

trade.at.open A logical vector of length one; default is TRUE.

tol A numeric vector of length one: only rebalance if the maximum absolute sug-

gested change for at least one position is greater than tol. Default is 0.00001

(which practically means always rebalance).

tol.p A numeric vector of length one: only rebalance those positions for which the

relative suggested change is greater than tol.p. Default is NA: always rebalance.

Globals A list of named elements. See Details.

prices0 A numeric vector (default is NULL). Only used if b is 0 and an initial portfolio

(initial.position) is specified.

include.data logical. If TRUE, all passed data are stored in final btest object. See Section

Value. See also argument include.timestamp.

include.timestamp

logical. If TRUE, timestamp is stored in final btest object. If timestamp is

missing, integers 1, 2, ... are used. See Section Value. See also argument

include.data.

timestamp a vector of timestamps, along prices (optional; mainly used for print method and

journal)

instrument character vector of instrument names (optional; mainly used for print method

and journal)

progressBar logical: display txtProgressBar?

variations a list. See Details.

variations.settings

a list. See Details.

replications an integer. If set, the function returns a list of btest objects. Each btest has an

attribute replication, which records the replication number.

Details

The function provides infrastructure for testing trading rules. Essentially, btest does accounting: keep track of transactions and positions, value open positions, etc. The ingredients are price timeseries (single series or OHLC bars), which need not be equally spaced; and several functions that map these series and other pieces of information into positions.

How btest works:

btest runs a loop from b + 1 to NROW(prices). In iteration t, a signal can be computed based on information from periods prior to t. Trading then takes place at the opening price of t.

t	time	open	high	low	close	
1	HH:MM:SS					<\
2	HH:MM:SS					< use information
3	HH:MM:SS					</td
4	HH:MM:SS	Χ				<- trade here
5	HH:MM:SS					

For slow-to-compute signals this is reasonable if there is a time lag between close and open. For daily prices, for instance, signals could be computed overnight. For higher frequencies, such as every minute, the signal function should be fast to compute. Alternatively, it may be better to use a larger time offset (i.e. use a longer time lag) and to trade at the close of t by setting argument trade.at.open to FALSE.

t	time	open	high	low	close	
1	HH:MM:SS					< \
2	HH:MM:SS					< use information
3	HH:MM:SS					< /
4	HH:MM:SS				Χ	< trade here
5	HH:MM:SS					

If no OHLC bars are available, a single series per asset (assumed to be close prices) can be used. trade.at.open will automaticall be set to FALSE.

The trade logic needs to be coded in the function signal. Arguments to that function must be named and need to be passed with Certain names are reserved and cannot be used as arguments: Open, High, Low, Close, Wealth, Cash, Time, Timestamp, Portfolio, SuggestedPortfolio, Globals. Further reserved names may be added in the future: it is suggested to not start an argument name with a capital letter.

The function signal must evaluate to the target position in units of the instruments. To work with weights, set convert.weights to TRUE, and btest will translate the weights into positions, based on the value of the portfolio at t-1.

Accessing data:

Within signal (and also other function arguments, such as do.signal), you can access data via special functions such as Close. These are automatically added as arguments to signal. Currently, the following functions are available: Open, High, Low, Close, Wealth, Cash, Time, Timestamp, Portfolio, SuggestedPortfolio, Globals. Globals is special: it is an environment, which can be used to persistently store data during the run of btest. Use the argument Globals to add initial objects. See the Examples below and the manual.

Additional functions may be added to btest in the future. The names of those functions will always be in title case. Hence, it is recommended to not use argument names for signal, etc. that start with a capital letter.

Replications and variations:

btest allows to run backtests in parallel. See the examples at https://enricoschumann.net/notes/parallel-backtests.html.

The argument variations.settings is a list with the following defaults:

method character: supported are "loop", "parallel" (or "snow") and "multicore"

```
load.balancing logical cores numeric
```

Value

A list with class attribute btest. The list comprises:

position actual portfolio holdings

suggested.position

suggested holdings (aka target position)

cash cash

wealth time-series of total portfolio value (aka equity curve)

cum.tc transaction costs

journal journal of trades. Only includes trades done during the backtest, not initial

positions.

initial.wealth initial wealth b burn-in

final.position final position if final.position is TRUE; otherwise NA

Globals environment Globals

When include.timestamp is TRUE, the timestamp is included. If no timestamp was specified, integers 1, 2, ... are used instead.

When include.data is TRUE, essentially all information (prices, instrument, the actual call and functions signal etc.) are stored in the list as well.

 DAX

Deutscher Aktienindex (DAX)

Description

Historical Prices of the DAX.

Usage

```
data("DAX")
```

Format

A data frame with 505 observations on the following variable:

DAX a numeric vector

Details

The DAX (*Deutscher Aktienindex*) is a stock-price index of the largest companies listed in Germany. The dataset comprises the close prices of the index for the years 2014 and 2015; dates are provided as rownames.

Examples

```
str(DAX)
summary(DAX)
```

drawdowns

Compute Drawdowns

Description

Compute drawdown statistics.

Usage

```
drawdowns(x, ...)
## Default S3 method:
drawdowns(x, ...)
## S3 method for class 'zoo'
drawdowns(x, ...)
```

12 drawdowns

Arguments

x a numeric vector of prices

... additional arguments, to be passed to methods

Details

drawdowns is a generic function. It computes drawdown statistics: maximum; and time of peak, trough and recovery.

Value

a data.frame:

peak peak before drawdown

trough lowest point

recover new high or NA if the drawdown has not been recovered yet

max the max drawdown

Author(s)

Enrico Schumann

References

https://enricoschumann.net/R/packages/PMwR/manual/PMwR.html#drawdowns-streaks

See Also

The actual computation of the drawdowns is done by function drawdown in package NMOF.

Series of uninterrupted up and down movements can be computed with streaks.

```
x <- c(100, 98)
drawdowns(x)

x <- c(100, 98, 102, 99)
dd <- drawdowns(x)
dd[order(dd$max, decreasing = TRUE), ]</pre>
```

instrument 13

instrument

Retrieve or Change Instrument

Description

Generic function for retrieving and changing instrument information.

Usage

```
instrument(x, ...)
instrument(x, ...) <- value</pre>
```

Arguments

```
x an object... arguments passed to methodsvalue an object
```

Details

Generic function: extract or, if meaningful, replace instrument information

Value

when used to extract instrument, a character vector

```
position
```

is_valid_ISIN

	-		T 0 T 1 1
10	V/2	וואו	TSTN

Validate Security Identification Numbers

Description

Check whether a given ISIN or SEDOL is valid.

Usage

```
is_valid_ISIN(isin, NA.FALSE = FALSE)
is_valid_SEDOL(SEDOL, NA.FALSE = FALSE)
```

Arguments

isin a character vector SEDOL a character vector

NA. FALSE logical: if TRUE, NA values evaluate to FALSE.

Details

Checks a character vector of ISINs and SEDOLs. The function returns TRUE if the ISIN/SEDOL is valid, else FALSE. Handling of NA is defined by argument NA. FALSE.

International Securities Identification Numbers (ISINs): The test procedure in ISO 6166 does not differentiate between cases. Thus, ISINs are transformed to uppercase before being tested.

Value

A named logical vector. For is_valid_SEDOL, a character vector is attached as an attribute note.

journal

Journal

Description

Create and manipulate a journal of financial transactions.

Usage

```
journal(amount, ...)
## Default S3 method:
journal(amount, price, timestamp, instrument,
        id = NULL, account = NULL, ...)
as.journal(x, ...)
is.journal(x)
## S3 method for class 'journal'
c(..., recursive = FALSE)
## S3 method for class 'journal'
length(x)
## S3 method for class 'journal'
aggregate(x, by, FUN, ...)
## S3 method for class 'journal'
print(x, ...,
      width = getOption("width"), max.print = getOption("max.print"),
      exclude = NULL, include.only = NULL)
## S3 method for class 'journal'
sort(x, decreasing = FALSE, by = "timestamp", ..., na.last = TRUE)
## S3 method for class 'journal'
summary(object, by = "instrument", drop.zero = TRUE,
```

```
na.rm = FALSE, ...)
## S3 method for class 'journal'
subset(x, ...)
## S3 method for class 'journal'
x[i, match.against = NULL,
ignore.case = TRUE, perl = FALSE, fixed = FALSE,
useBytes = FALSE, ..., invert = FALSE]
## S3 replacement method for class 'journal'
x[i, match.against = NULL,
ignore.case = TRUE, ..., invert = FALSE] <- value</pre>
## S3 method for class 'journal'
as.data.frame(x, row.names = NULL, optional = FALSE, ...)
## S3 method for class 'journal'
head(x, n = 6L, ..., by = "instrument")
## S3 method for class 'journal'
tail(x, n = 6L, ..., by = "instrument")
```

Arguments

timestamp An atomic vector of mode numeric or character. Timestamps should typically

be sortable.

amount numeric price numeric

instrument character or numeric (though typically character)

id An atomic vector. Default is NULL.account An atomic vector. Default is NULL.

... For journal: further arguments, which must all be named.

For subset: an expression that evaluates to a logical vector. The expression

may use all fields of the passed journal; see Examples.

For `[`: arguments other than ignore.case to be passed to grep.

For sort: arguments passed to sort.

x a journal or an object to be coerced to class journal (for as. journal) or to

be checked if it inherits from journal (for is. journal)

object a journal

width integer. See options.

decreasing passed to sort

by sort: sort by field. head/tail: by field (default is instrument). summary: a vec-

tor of keywords (or NULL); supported are "instrument", "year" and "month".

na.rm logical drop.zero logical

na.last arguments passed to sort

max.print maximum number of transactions to print exclude character: fields that should not be printed

include.only character: print only those fields. (Not supported yet.)

row.names see as.data.frame
optional see as.data.frame
recursive ignored (see c)

i integer, logical or character. The latter is interpreted as a regexp (see grep)

n integer

match.against character vector of field names. Default is NULL, which means to match against

all character fields.

ignore.case logical: passed to grep1 logical: passed to grep1 fixed logical: passed to grep1 useBytes logical: passed to grep1

invert logical. If TRUE, invert selection (when i is of mode character, select journal

entries that do not match regular expression)

FUN either a function that takes as input a journal and evaluates to a journal, or a list

of named functions

value a replacement value

Details

The journal function creates a list of its arguments and attaches a class attribute ('journal'). It is a generic function; the default method creates a journal from atomic vectors. The btest method extracts the journal from the results of a backtest; see btest.

as.journal coerces an object to a journal and is primarily used for creating a journal from a data.frame. Calling as.journal on an unnamed numeric vector interprets the vector as amounts. If the vector is named, these are interpreted as instruments; see Examples. Calling as.journal on a journal returns the journal itself.

journal methods are available for several generic functions, for instance:

all.equal compare contents of two journals

aggregate Splits a journal according to by, applies a function to every sub-journal and recombines the results into a journal.

as.data.frame Coerce journal to data.frame.

c Combine several journals into one. Note that the first argument to c. journal must inherit from journal, or else the method dispatch will fail. For empty journals, use journal() (not NULL).

length number of transactions in a journal; it uses the length of amount

split Splits a journal according to f, yielding a list of journals. Often used interactively to have information per sub-journal printed.

subset evaluates an expression in an environment that can access all fields of the journal. The function is meant for interactive analysis; care is needed when it is used within other functions: see Examples and the Manual.

summary provides summary statistics, such as number of trades and average buy/sell prices toOrg converts a journal to an Org table; package **orgutils** must be available

For journals that have a length, missing arguments will be coded as NA except for id and account, which become NULL. In zero-length (i.e. 'empty') journals, all fields have length 0. A zero-length journal is created, for instance, by saying journal() or when an zero-row data. frame is passed to as.journal.

Value

An object of class journal, which is a list of atomic vectors.

20 NAV series

NAVseries

Net-Asset-Value (NAV) Series

Description

Create a net-asset-value (NAV) series.

Usage

```
NAVseries(NAV, timestamp,
          instrument = NULL, title = NULL,
          description = NULL,
          drop.NA = NULL)
as.NAVseries(x, ...)
## S3 method for class 'NAVseries'
print(x, ..., na.rm = FALSE)
## S3 method for class 'NAVseries'
summary(object, ..., monthly.vol = TRUE,
        bm = NULL, monthly.te = TRUE,
        na.rm = FALSE, assume.daily = FALSE)
## S3 method for class 'NAVseries'
plot(x, y, ..., xlab = "", ylab = "", type = "l")
## S3 method for class 'NAVseries'
window(x, start = NULL, end = NULL, ...)
## S3 method for class 'summary.NAVseries'
as.data.frame(x, ...)
```

NAVseries 21

Arguments

NAV numeric

timestamp time stamp, typically Date or POSIXct

instrument character title character description character

x an NAV series or an object to be coerced to NAV series

object an NAVseries

further arguments. For summary, these can be NAVseries.

drop.NA logical. If NAV is the result of calling btest, then this controls whether unused

initial observations ('burnin') are dropped.

bm an optional NAV series. If bm does not inherit from NAV series, as .NAV series

is tried.

monthly.vol if TRUE (default), volatility computations are done on monthly returns monthly.te if TRUE (default), tracking-error computations are done on monthly returns

assume.daily logical na.rm logical

y a second NAV series to be plotted. Not supported yet.

xlab character. See plot.
ylab character. See plot.
type character. See plot.

start same class as timestamp; NULL means the first timestamp end same class as timestamp; NULL means the last timestamp

Details

NAV series:

An NAV series is a numeric vector (the actual series) and additional information, attached as attributes: timestamp, instrument, title, description. Of these attributes, timestamp is the most useful, as it is used for several computations (e.g. when calling summary) and for plotting.

The 'instrument' is typically an internal label used to identify the series, such as a ticker; 'title' is a label, too, but is intended to be human-readable; 'description' finally should be human-readable as well, but may be longer than 'title'.

Summaries:

The summary method returns a list of the original NAV series plus various statistics, such as return per year and volatility. The method may receive several NAV series as input.

Value

an NAVseries: see Details.

an NAVseries summary: a list of lists. If a benchmark series is present, the summary has an attribute bm: an integer, specifying the position of the benchmark.

Note

The semantics of handling NAVseries are not stable yet. Currently, objects of class NAVseries are univariate: you create a single NAVseries, summarise it, plot it, and so one. In the future, at least some of the methods will support the multi-variate case, i.e. be able to handle several series at once.

Examples

pl

Profit and Loss

Description

Compute profit and (or) loss of financial transactions.

Usage

```
pl(amount, ...)
## Default S3 method:
pl(amount, price, timestamp = NULL,
   instrument = NULL, multiplier = 1,
   multiplier.regexp = FALSE,
   along.timestamp = FALSE, approx = FALSE,
   initial.position = NULL, initial.price = NULL,
   vprice = NULL, tol = 1e-10, do.warn = TRUE,
   do.sum = FALSE, pl.only = FALSE,
   footnotes = TRUE, ...)
## S3 method for class 'journal'
```

Arguments

amount numeric or a journal

price numeric

instrument character or numeric (though typically character)

timestamp An atomic vector of mode numeric or character. Timestamps should typically

be sortable.

along.timestamp

logical; or a vector of timestamps. If the latter, vprice must be specified as well. See the vignette "Profit/Loss for Open Positions" (pl_open_positions) for details. Timestamps must be in ascending order and will be sorted if they are

not (and vprice will then be sorted as well).

initial.position

a position

initial.price prices to evaluate initial position

vprice valuation price; a numeric vector. With several instruments, the prices must be

named, e.g. c(stock1 = 100, stock2 = 101). See Details.

multiplier numeric vector. When instrument is specified and the vector is named, the

names will be matched against instruments.

multiplier.regexp

logical. If TRUE, the names of multiplier are interpreted as regular expressions.

See Examples.

approx logical

tol numeric: threshold to consider a position zero.

x a pl object to be printed or to be coerced to a data.frame

... further argument

use.crayon logical

na.print character: how to print NA values

do.warn logical: issue warnings?

do.sum logical: sum profit/loss across instruments?

pl.only logical: if TRUE, return only numeric vector of profit/loss

footnotes logical, with default TRUE: collect and print notes?

Details

Computes profit and/or loss and returns a list with several statistics (see Section Value, below). To get only the profit/loss numbers as a numeric vector, set argument pl.only to TRUE.

pl is a generic function: The default input is vectors for amount, price, etc. Alternatively (and often more conveniently), the function may also be called with a journal or a data.frame as its input. For data frames, columns must be named amount, price, and so on, as in a journal.

pl may be called in two ways: either to compute *total profit/loss* from a list of trades, possibly broken down by instrument and account; or to compute *profit/loss over time*. The latter case typically requires setting arguments along.timestamp and/or vprice (see Examples). Profit/loss over time is always computed with time in ascending order: so if the timestamps in along.timestamp are not sorted, the function will sort them (and vprice as well).

Using vprice: when along.timestamp is logical (FALSE or TRUE), vprice can be used to value an open position. For a single asset, it should be a single number; for several assets, it should be named vector, with names indicating the instrument. When along.timestamp is used to pass a custom timestamp: for a single asset, vprice must be a vector with the same length as along.timestamp; for several assets, it must be a numeric matrix with dimension length(along.timestamp) times number of assets.

.pl and .pl_stats are helper functions that are called by pl. .pl_stats requires amount and price to be sorted in time, and to be of length > 0.

To use package **crayon** – which is only sensible in interactive use –, either explicitly set use. crayon to TRUE or set an option PMwR.use.crayon to TRUE.

Value

For pl, an object of class pl, which is a list of lists: one list for each instrument. Each such list contains numeric vectors: pl, realised, unrealised, buy, sell, volume. If along. timestamp is not FALSE, a vector timestamp is also present.

For .pl, a numeric vector with four elements: profit/loss in units of the instrument, sum of absolute amounts, average buy price, average sell price. For zero-length vector, the function evaluates to c(0, 0, NaN, NaN).

For .pl_stats, a list of two elements: the average entry-price, and the realized profit/loss. profit/loss in units of the instrument, sum of absolute amounts, average buy price, average sell price. For zero-length vector, the function evaluates to c(0, 0, NaN, NaN).

plot_trading_hours

Plot Time Series During Trading Hours

Description

Plot a time series after removing weekends and specific times of the day.

Usage

Arguments

x A numeric vector. Can also be of class zoo.

t A vector that inherits from class POSIXt. If x inherits from class zoo, then index(x) is used (and any supplied value for t is ignored).

interval A character string like "num units", in which num is a number, and units is "sec", "min", "hour" or "day". The space between num and units is mandatory.

28 plot_trading_hours

labels A character vector of length one, determining the grid for plot_trading_hours:

can be "hour", "day", "dayhour" or "month".

label.format See strftime.

exclude.weekends

logical: default is TRUE

holidays a vector of class Date or a character vector in a format that is understood by

as.Date.

fromHHMMSS a character vector of length one in format "HHMMSS" toHHMMSS a character vector of length one in format "HHMMSS" do.plot.axis logical. Should axis(1) be plotted? Default is TRUE.

... parameters passed to plot (and typically par)

from POSIXct: start plot at (if not specified, plot starts at first data point) to POSIXct: end plot at (if not specified, plot ends at last data point)

do.plot logical. Should anything be plotted? Default is TRUE. If FALSE, the function

returns a list of points.

axis1.par a list of named elements

Details

Plot a timeseries during specific times of day.

Value

A list (invisibly if do.plot is TRUE):

list(t, x, axis.pos = pos, axis.labels, timegrid)

t positions x values

axis.pos positions of x-tickmarks

axis.labels labels at x-ticks timegrid a POSIXct vector

map a function. See the manual (a link is under References).

DateTimeClasses

Examples

position

Aggregate Transactions to Positions

Description

Use information on single trades to compute a position at a specific point in time.

Usage

30 position

Arguments

when a timestamp or a vector of timestamps; alternatively, several keywords are supported. See Details. numeric or an object of class journal. If amount is a one-dimensional array, amount the dimension is dropped. timestamp numeric or character: timestamps, must be sortable instrument character: symbols to identify different instruments account character: description of account. Ignored if NULL. use.account logical. If TRUE, positions are computed by account and instrument; otherwise by instrument only. use.names logical or NULL. The argument handles whether names of amount are used as instruments. If NULL: if amount is named and instrument is not specified, names of amount are interpreted as instruments. If use.names is FALSE, names of amount are ignored. (Ignoring names was the default behaviour prior to PMwR version 0.11.) drop.zero If logical, drop instruments that have a zero position; default is FALSE. If numeric, it is used as a tolerance; e.g., a value of 1-e12 will drop any position whose absolute amount is smaller than 1-e12. An object of type position. Х

Details

sep

position computes positions for lists of trades. position is a generic function; most useful is the method for journals.

A regular expression. Split instruments accordingly. Not implemented yet.

arguments passed to print

The function checks if timestamp is sorted (see is.unsorted) and sorts the journal by timestamp, if required. If there are (some) NA values in timestamp, but timestamp is sorted otherwise, the function will proceed (with a warning, though).

The argument when can also be specified as one of several keywords: last (or newest or latest) provides the position at the latest timestamp; first (or oldest) provides the position at the earliest timestamp; all provides the positions at all timestamps in the journal. endofday, endofmonth and endofyear provide positions at the end of all calendar days, months and years within the timestamp range of the journal. The latter keywords can only work if timestamp can be coerced to Date.

Computing with positions:

Several mathematical operators work specially for positions. Unary +/- work directly on positions, whereas unary ! returns a logical vector of the same dimensions as the initial position. (So !!<position> shows whether a position is non-zero.)

Binary operations, such as +, - or >, work if both positions have the same timestamps (which includes the case in which the timestamp of both is NA). Multiplication produces an error. Instruments can differ, but must be non-NA, except for the special case of length-one NA.

position 31

Value

An object of class position, which is a numeric matrix with instrument and timestamp attributes. Note that position will never drop the result's dim attribute: it will always be a matrix of size length(when) times length(unique(instrument)), which may not be obvious from the printed output. (An operation such as < or ! results in a logical matrix of the same dimension.) The rows of the matrix correspond to timestamps; the columns correspond to instruments.

To extract the numeric position matrix, use as.matrix(p).

32 pricetable

pricetable

Price Table

Description

Create price table

Usage

```
pricetable(price, ...)
```

Arguments

price a matrix

... further arguments, passed to methods

Details

pricetable is a helper function for extracting prices of particular instrument at specified dates. For this, it first creates a table that merges series passed via ... and appends a class attribute. A [method then allows to extract prices. Importantly, if you ask for a subset of m rows and n columns, the result will be a matrix of size m times n, even if times or instruments are missing.

pricetable is a generic function, currently with methods for numeric vectors (including vectors with a dim, aka matrices) and for zoo objects.

Value

a numeric matrix with class attribute pricetable

quote32

Treasury Quotes with 1/32nds of Point

Description

Print treasury quotes with 1/32nds of points.

34 quote32

Usage

```
quote32(price, sep = "(-|'|:)", warn = TRUE)
q32(price, sep = "(-|'|:)", warn = TRUE)
```

Arguments

price numeric or character. See Details.

sep character: a regular expression

warn logical. Warn about rounding errors?

Details

The function is meant for pretty-printing of US treasury bond quotes; it provides no other functionality.

If price is numeric, it is interpreted as a quote in decimal notation and 'translated' into a price quoted in fractions of a point.

If price is character, it is interpreted as a quote in fractional notation.

q32 is a short-hand for quote32.

Value

A numeric vector of class quote32.

Author(s)

Enrico Schumann

References

CME Group (2020). Treasury Futures Price Rounding Conventions.

```
quote32(100 + 17/32 + 0.75/32)
q32("100-172")

q32("100-272") - q32("100-270")
as.numeric(q32("100-272") - q32("100-270"))
```

rc 35

rc Return Contribution

Description

Return contribution of portfolio segments.

Usage

```
rc(R, weights, timestamp, segments = NULL,
   R.bm = NULL, weights.bm = NULL,
   method = "contribution",
   linking.method = NULL,
   allocation.minus.bm = TRUE,
   tol = sqrt(.Machine$double.eps))
```

Arguments

R returns: a numeric matrix. Rows are time periods; columns are assets.

weights the segment weights: a numeric matrix. weights[i, j] must correspond to

R[i, j]

timestamp character or numeric

segments character. If missing, column names of R or of weights are used (if they are not

NULL).

method a string; default is contribution, and also supported are attribution, bottomup

or topdown

linking.method NULL or a string. Currently supported are 0-cumulative, 1-cumulative, 0.5-cumulative

(geometric $\{0,1,0.5\}$) and logarithmic. See Examples.

allocation.minus.bm

logical

tol numeric: weights whose absolute value is below tol are considered zero and

not used for computations. Ignored if NA.

If portfolio returns are to be compared against benchmark returns, benchmark returns and weights must be supplied:

R.bm benchmark returns: a numeric matrix

weights.bm the benchmark weights of segments: a numeric matrix. weights.bm[i, j] must

correspond to R.bm[i, j]

Details

The function computes segment contribution, potentially over time. Returns and weights must be arranged in matrices, with rows corresponding to time periods and columns to portfolio segments. If weights and R are atomic vectors, then they are interpreted as cross-sectional weights/returns for a single period, i.e. they are handled like row vectors.

36 rc

Weights can be missing, in which case R is assumed to already comprise segment returns.

Note that the segment contributions need not come from asset classes; the computation works for any additive single-period decomposition of portfolio returns.

Value

```
For method contribution, a list of two components:

period_contributions

a data.frame of single-period contributions, sorted in time total_contributions

a numeric vector
```

rebalance

Rebalance Portfolio

Description

Compute the differences between two portfolios.

Usage

```
rebalance(current, target, price,
          notional = NULL, multiplier = 1,
          truncate = TRUE, match.names = TRUE,
          fraction = 1, drop.zero = FALSE,
          current.weights = FALSE,
          target.weights = TRUE)
## S3 method for class 'rebalance'
print(x, ..., drop.zero = TRUE)
replace_weight(weights, ..., prefix = TRUE, sep = "::")
```

Arguments

current the current holdings: a (typically named) vector of position sizes; can also be a

position

the target holdings: a (typically named) vector of weights; can also be a position target

a numeric vector: the current prices; may be named price

notional a single number: the value of the portfolio; if missing, replaced by sum(current*prices)

multiplier numeric vector, possibly named

truncate truncate computed positions? Default is TRUE.

match.names logical fraction numeric

an object of class rebalance.

rebalance: arguments passed to print; replace_weight: numeric vectors logical: should instruments with no difference between current and target be drop.zero

included?

Note the different defaults for computing and printing.

current.weights

logical. If TRUE, the values in current are interpreted as weights. If FALSE, current is interpreted as a position (i.e. notional/number of contracts).

rebalance 39

target.weights logical. If TRUE (the default), the values in target are interpreted as weights. If

FALSE, target is interpreted as a position (i.e. notional/number of contracts).

weights a numeric vector with named components

sep character prefix logical

Details

The function computes the necessary trades to move from the current portfolio to a target portfolio.

replace_weight is a helper function to split baskets into their components. All arguments passed via ... should be named vectors. If names are not syntactically valid (see make.names), quote them. The passed vectors themselves should be passed as named arguments: see Examples.

Value

An object of class rebalance, which is a data. frame:

instrument character, or NA when match.names is FALSE

price prices

current current portfolio, in units of instrument target new portfolio, in units of instrument

difference the difference between current and target portfolio

Attached to the data.frame are several attributes:

notional a single number

match.names logical

multiplier a numeric vector with as many elements as the resulting data.frame has rows

```

returns

Compute Returns

Description

Convert prices into returns.

Usage

```
returns(x, ...)
## Default S3 method:
returns(x, t = NULL, period = NULL, complete.first = TRUE,
       pad = NULL, position = NULL,
       weights = NULL, rebalance.when = NULL,
       lag = 1, na.rm = FALSE, ..., na.warn = FALSE)
## S3 method for class 'zoo'
returns(x, period = NULL, complete.first = TRUE,
       pad = NULL, position = NULL,
       weights = NULL, rebalance.when = NULL, lag = 1, na.rm = FALSE, ...)
## S3 method for class 'p_returns'
print(x, ..., year.rows = TRUE, month.names = NULL,
      zero.print = "0", plus = FALSE, digits = 1,
     na.print = NULL)
## S3 method for class 'p_returns'
toLatex(object, ...,
       year.rows = TRUE, ytd = "YTD", month.names = NULL,
```

```
eol = "\\\", stand.alone = FALSE)
## S3 method for class 'p_returns'
toHTML(x, ...,
       year.rows = TRUE, ytd = "YTD", month.names = NULL,
       stand.alone = TRUE, table.style = NULL, table.class = NULL,
       th.style = NULL, th.class = NULL,
       td.style = "text-align:right; padding:0.5em;",
       td.class = NULL, tr.style = NULL, tr.class = NULL,
       browse = FALSE)
.returns(x, pad = NULL, lag)
```

Arguments

х

for the default method, a numeric vector (possibly with a dim attribute; i.e. a matrix) of prices. returns also supports x of other classes, such as zoo or NAVseries. For time-series classes, argument t should be NULL.

For .returns, x must be numeric (for other classes, .returns may not work properly).

t

timestamps. See arguments period and rebalance. when.

period

Typically a string. Supported are "hour", "day", "month", "quarter", "year", "ann" (annualised), "ytd" (year-to-date), "mtd" (month-to-date), "itd" (inceptionto-date) or a single year, such as "2012". Instead of "itd", "total" may also be used. The value of 'period' is used only when timestamp information is available: for instance, when t is not NULL or with zoo/xts objects. The exception is "itd", which can be computed without timestamp information. Holding period "ytd" produces a warning if the current year (as obtained from Sys. Date) differs from the latest timestamp of the series. Specifying period as "ytd!" suppresses the warning.

All returns are computed as simple returns. They will only be annualised with option "ann"; they will not be annualised when the length of the time series is less than one year. To force annualising in such a case, use "ann!". Annualisation can only work when the timestamp t can be coerced to class Date. The result will have an attribute is. annualised, which is a logical vector of length one. Day-count convention for annualisation is act/365.

complete.first logical. For holding-period returns such an monthly or yearly, should the first period (if incomplete) be used.

pad

either NULL (no padding of initial lost observation) or a value used for padding (reasonable values might be NA or 0)

na.rm

logical; see Details

na.warn

logical

position

either a numeric vector of the same length as the number of assets (i.e. ncol(x)), or a numeric matrix whose dimensions match those of prices (i.e. dim(x) must equal dim(weights)), or a matrix with as many rows as rebalance. when has elements

weights either a numeric vector of the same length as the number of assets (i.e. ncol(x)),

or a numeric matrix whose dimensions match those of prices (i.e. $\dim(x)$ must equal $\dim(\text{weights})$), or a matrix with as many rows as rebalance.when has

elements

rebalance. when a logical vector or a vector of integers indicating the x at which to rebalance. If

x inherits from a time-series class (such as zoo), it may also be of the same class

as the time index of x.

... further arguments to be passed to methods

year.rows logical. If TRUE (the default), print monthly returns with one row per year.

zero.print character. How to print zero values.

na.print character. How to print NA values. (Not supported yet.)

plus logical. Add a '+' before positive numbers? Default is FALSE.

lag The lag for computing returns. A positive integer, defaults to one; ignored for

time-weighted returns or if t is supplied.

object an object of class p_returns ('period returns')

month.names character: names of months. Default is an abbreviated month name as provided

by the locale. That may cause trouble, notably with toLatex, if such names contain non-ASCII characters: a safe choice is either the numbers 1 to 12, or the

character vector month. abb, which lives in the base package.

digits number of digits in table

ytd header for YTD

eol character

stand.alone logical or character

table.class character table.style character th.class character th.style character td.class character td.style character tr.class character tr.style character

browse logical: open table in browser?

Details

returns is a generic function. It computes simple returns: current values divided by prior values minus one. The default method works for numeric vectors/matrices. The function .returns does the actual computations and may be used when a 'raw' return computation is needed.

Holding-Period Returns:

When a timestamp is available, returns can compute returns for specific calendar periods. See argument period.

Portfolio Returns:

returns may compute returns for a portfolio specified in weights or position. The portfolio is rebalanced at rebalance.when; the default is every period. Weights need not sum to one. A zero-weight portfolio, or a portfolio that never rebalances (e.g. with rebalance.when set to FALSE), will result in a zero return.

rebalance.when may either be logical, integers or of the same class as a timestamp (e.g. Date).

Handling missing values:

Removing NAs (by setting na.rm to TRUE) is limited to the following types of holding-period returns: ann, total/itd, ytd, mtd. In each case, the first and latest available finite values are used for computing returns. For multivariate series x, this can lead to returns being computed for differing periods.

Value

If called as returns(x): a numeric vector or matrix, possibly with a class attribute (e.g. for a zoo series).

If called with a period argument: an object of class "p_returns" (period returns), which is a numeric vector of returns with attributes t (timestamp) and period. Main use is to have methods that pretty-print such period returns; currently, there are methods for toLatex and toHTML.

In some cases, additional attributes may be attached: when portfolio returns were computed (i.e. argument weights was specified), there are attributes holdings and contributions. For holding-period returns, there may be a logical attribute is.annualised, and an attribute from to, which tells the start and end date of the holding period.

Daily prices.

Examples

```
str(REXP)
```

scale1

Scale Time Series

Description

Scale time series so that they can be better compared.

Usage

Arguments

X	a time series
when	origin: for the default method, either a string or numeric (integer). Allowed strings are "first.complete" (the default), "first", and "last". For the zoo method, a value that matches the class of the index of x; for instance, with an index of class Date, when should inherit from Date.
level	numeric
centre	logical
scale	logical or numeric
geometric	logical: if TRUE (the default), the geometric mean is deducted with centre is TRUE; if FALSE, the arithmetic mean is used
inflate	numeric: an annual rate at which the series is inflated (or deflated if negative)
total.g	numeric: to total growth rate (or total return) of a series
	other arguments passed to methods

46 streaks

Details

scale1(cumprod(1 + c(0, rnorm(20, sd = 0.02))), level = 100)
```

streaks

Up and Down Streaks

Description

Compute up and down streaks for time-series.

Usage

streaks 47

Arguments

x a price series
initial.state NA, "up" or "down"
up a number, such as 0.1 (i.e. 10%)

down a negative number, such as -0.1 (i.e. -10%)

y another price series

bm another price series. Mapped to 'y' in the default method.

relative logical

... other arguments passed to methods

Details

streaks is a generic function. It computes series of uninterrupted up and down movements ('streaks') in a price series. Uninterrupted is meant in the sense that no countermovement of down (up) percent or more occurs in up (down) movements.

There are methods for numeric vectors, and NAVseries and zoo objects.

The turning points (extreme points) are computed with the benefit of hindsight: the starting point (the low) of an up streak can only be determined once the streak is triggered, i.e. the up streak has already run its minimum amount. Vice versa for down streaks.

When 'up' and 'down' are not equal, results may be inconsistent: in the current implementation, streaks alternates between up and down streaks. Suppose up is large compared with down, i.e. it takes long to trigger up streaks, but they are easily broken. Down streaks, on the other hand, are quickly triggered but rarely broken. Now suppose that a down streak is broken by an up streak: it may then well be that the up streak would never have been counted as such, because it was actually broken itself by another down streak. The implementation for differing values of 'up' and 'down' may change in the future.

Value

A data.frame:

start beginning of streak end end of streak state up, down or NA

return, change the return over the streak. If y was specified, geometric excess return is com-

puted (see Examples). If relative is FALSE, the column is named change.

## (y[results$end]/y[results$start]) - 1
```

toHTML

Import from package textutils

Description

The toHTML function is imported from package **textutils**. Help is available at textutils::toHTML. Say library("textutils") in your code to use the function.

Trade-Analysis

Analysing Trades: Compute Profit/Loss, Resize and more

Description

Functions to help analyse trades (as opposed to profit-and-loss series)

Usage

Trade-Analysis 49

Arguments

amount notionals

price a vector of prices

 $\begin{array}{ll} \mbox{timestamp} & \mbox{a vector.} \\ \mbox{aggregate} & \mbox{TRUE or FALSE} \end{array}$

fun a function

1im a maximum absolute position size

start optional time end optional time

drop.zero logical. If TRUE, trades with zero amounts are removed. See Examples.

abs.value logical. If TRUE, the absolute exposure is computed.

... passed on to fun

tol numeric

Details

scale_trades takes a vector of notionals, prices and scales all trades along the paths so that the maximum exposure is 1.

The default fun divides every element of a vector n by max(abs(cumsum(n))). If user-specified, the function fun needs to take a vector of notionals (changes in position.)

split_trades decomposes a trade list into single trades, where a single trade comprises those trades from a zero position to the next zero position. Note that the trades must be sorted chronologically.

Value

Either a list or a list-of-lists.

Author(s)

Enrico Schumann

split_trades(amount = dS[!zero], price = P[!zero], timestamp = t[!zero])</pre>
```

unit_prices

Compute Prices for Portfolio Based on Units

Description

Compute prices for a portfolio based on outstanding shares (units).

Usage

Arguments

NAV	a dataframe of two columns: timestamp and net asset value. There should be no duplicated timestamps. Column names are ignored; the function assumes timestamp is the first column, NAV the second.
cashflows	a data.frame of two or three columns: timestamp, cashflow and (optionally) an id or account. Column names are ignored; the function assumes timestamp is the first column, the external cashflows the second, and an account/id the third.
initial.price	initial price; ignored when initial.units is not zero
initial.units	number of outstanding units before first cashflow
cf.included	logical. If TRUE (the default), it is assumed that the NAV series at the time of the cashflow already includes the cashflow.
round.price	round unit prices: NULL (no rounding) or an integer
round.units	round number of units: NULL (no rounding) or an integer

unit_prices 51

Details

This function is experimental, and its interface is not stable yet.

The function may be used to compute the returns for a portfolio with external cashflows, i.e. what is usually called time-weighted returns. Note that 'cashflows' can also comprise other positions that are added or removed from the portfolio without affecting performance.

Value

A data. frame with one row for each row in NAV:

timestamp the timestamp, as provided in argument NAV total NAV, as provided in argument NAV price NAV per unit outstanding units (i.e. shares) *after* cashflows

Attached as an attribute is a data. frame transactions, with as many rows as the provided argument cashflows, which provides the number of units created/destroyed for each cashflow.

valuation

Valuation

Description

Valuation of financial objects: map an object into a quantity that is measured in a concrete (typically currency) unit.

Usage

Arguments

x	an object
multiplier	a numeric vector, typically with named elements
cashflow	either a numeric vector or a function that takes on argument (a journal) and transforms it into a numeric vector
instrument	either a character vector or a function that takes on argument (a journal) and transforms it into a character vector

valuation 53

flip.sign logical. If TRUE (the default), a positive amount gets mapped into a negative cashflow. numeric: a matrix whose elements correspond to those in x. If only a single vprice timestamp is used and the position is named, this may also be a named numeric vector; see Examples. The argument behaves like vprice in pl; but for valuation those prices need not be sorted in time. logical: sum over positions do.sum use.names logical: use names of vprice? price.unit a named character vector. Not implemented. verbose logical

do.warn logical

... other arguments passed to methods

Details

This function is experimental, and the methods' interfaces are not stable yet.

valuation is a generic function. Its semantics suggest that an object (e.g. a financial instrument or a position) is mapped into a concrete quantity (such as an amount of some currency).

The journal method transforms the transactions in a journal into amounts of currency (e.g, a sale of 100 shares of a company is transformed into the value of these 100 shares).

The position method takes a position and returns the value (in currency units) of the position.

Value

depends on the object: for journals, a journal
