

Package ‘TreeSearch’

August 23, 2025

Title Phylogenetic Analysis with Discrete Character Data

Version 1.7.0

License GPL (>= 3)

Copyright Incorporates C/C++ code from Morphy Phylogenetic Library by Martin Brazeau <<https://github.com/mbrazeau/MorphyLib>> (GPL3)

Description Reconstruct phylogenetic trees from discrete data. Inapplicable character states are handled using the algorithm of Brazeau, Guillaume and Smith (2019) <[doi:10.1093/sysbio/syy083](https://doi.org/10.1093/sysbio/syy083)> with the ``Morphy'' library, under equal or implied step weights. Contains a ``shiny'' user interface for interactive tree search and exploration of results, including character visualization, rogue taxon detection, tree space mapping, and cluster consensus trees (Smith 2022a, b) <[doi:10.1093/sysbio/syab099](https://doi.org/10.1093/sysbio/syab099)>, <[doi:10.1093/sysbio/syab100](https://doi.org/10.1093/sysbio/syab100)>. Profile Parsimony (Faith and Trueman, 2001) <[doi:10.1080/10635150118627](https://doi.org/10.1080/10635150118627)>, Successive Approximations (Farris, 1969) <[doi:10.2307/2412182](https://doi.org/10.2307/2412182)> and custom optimality criteria are implemented.

AdditionTree	<i>Addition tree</i>
--------------	----------------------

Description

Generates a starting tree by adding each taxon in turn to the most parsimonious location.

Usage

```
AdditionTree(dataset, concavity = Inf, constraint, sequence)
```

Arguments

dataset	A phylogenetic data matrix of phangorn class <code>phyDat</code> , whose names correspond to the labels of any accompanying tree. Perhaps load into R using ReadAsPhyDat . Additive (ordered) characters can be handled using Decompose .
concavity	Determines the degree to which extra steps beyond the first are penalized. Specify a numeric value to use implied weighting (Goloboff 1993); <code>concavity</code> specifies k in $k / e + k$. A value of 10 is recommended; TNT sets a default of 3, but this is too low in some circumstances (Goloboff et al. 2018; Smith 2019). Better still explore the sensitivity of results under a range of concavity values, e.g. $k = 2^{(1:7)}$. Specify <code>Inf</code> to weight each additional step equally, (which underperforms step weighting approaches (Goloboff et al. 2008; Goloboff et al. 2018; Goloboff and Arias 2019; Smith 2019)). Specify "profile" to employ an approximation of profile parsimony (Faith and Trueman 2001).

constraint	Either an object of class <code>phyDat</code> , in which case returned trees will be perfectly compatible with each character in <code>constraint</code> ; or a tree of class <code>phylo</code> , all of whose nodes will occur in any output tree. See ImposeConstraint() and vignette for further examples.
sequence	Character or numeric vector listing sequence in which to add taxa. Randomized if not provided.

Value

`AdditionTree()` returns a tree of class `phylo`, rooted on `sequence[1]`.

Examples

```
data("inapplicable.phyData", package = "TreeSearch")
AdditionTree(inapplicable.phyData[["Longrich2010"]], concavity = 10)
```

AllSPR

All SPR trees

Description

All SPR trees

Usage

```
AllSPR(parent, child, nEdge, notDuplicateRoot, edgeToBreak)
```

Arguments

parent	Integer vector corresponding to the first column of the edge matrix of a tree of class <code>phylo</code> , i.e. <code>tree[["edge"]][, 1]</code>
child	Integer vector corresponding to the second column of the edge matrix of a tree of class <code>phylo</code> , i.e. <code>tree[["edge"]][, 2]</code> .
nEdge	integer specifying the number of edges of a tree of class <code>phylo</code> , i.e. <code>dim(tree\$edge)[1]</code>

notDuplicateRoot

logical vector of length nEdge, specifying for each edge whether it is the second edge leading to the root (in which case its breaking will be equivalent to breaking the other root edge... except insofar as it moves the position of the root.)

edgeToBreak

(optional) integer specifying the index of an edge to bisect/prune, generated randomly if not specified. Alternatively, set to -1 to return a complete list of all trees one step from the input tree.

Value

AllSPR() returns a list of edge matrices for all trees one SPR rearrangement from the starting tree

Author(s)

Martin R. Smith

Carter1

Number of trees with m steps

Description

Calculate the number of trees in which Fitch parsimony will reconstruct m steps, where a leaves are labelled with one state, and b leaves are labelled with a second state.

Usage

Carter1(m, a, b)

Log2Carter1(m, a, b)

LogCarter1(m, a, b)

Arguments

m Number of steps.

a, b Number of leaves labelled 0 and 1.

Details

Implementation of theorem 1 from Carter et al. (1990)

Author(s)

Martin R. Smith (martin.smith@durham.ac.uk)

Examples

```
# The character `0 0 0 1 1 1`
Carter1(1, 3, 3) # Exactly one step
Carter1(2, 3, 3) # Two steps (one extra step)

# Number of trees that the character can map onto with exactly _m_ steps
# if non-parsimonious reconstructions are permitted:
cumsum(sapply(1:3, Carter1, 3, 3))

# Three steps allow the character to map onto any of the 105 six-leaf trees.
```

CharacterLength	<i>Character length</i>
-----------------	-------------------------

Description

Homoplasy length of each character in a dataset on a specified tree.

Usage

```
CharacterLength(tree, dataset, compress = FALSE)
```

```
FitchSteps(tree, dataset)
```

```
FastCharacterLength(tree, dataset)
```

Arguments

tree	A tree of class phylo .
dataset	A phylogenetic data matrix of phangorn class phyDat, whose names correspond to the labels of any accompanying tree. Perhaps load into R using ReadAsPhyDat . Additive (ordered) characters can be handled using Decompose .
compress	Logical specifying whether to retain the compression of a phyDat object or to return a vector specifying to each individual character, decompressed using the dataset's index attribute.

Value

CharacterLength() returns a vector listing the contribution of each character to tree score, according to the algorithm of Brazeau et al. (2019).

Functions

- [FastCharacterLength\(\)](#): Do not perform checks. Use with care: may cause erroneous results or software crash if variables are in the incorrect format.

tree <- TreeTools::NJTree(dataset)
CharacterLength(tree, dataset)
CharacterLength(tree, dataset, compress = TRUE)
```

ClusterStrings	<i>Cluster similar strings</i>
----------------	--------------------------------

Description

Calculate string similarity using the Levenshtein distance and return clusters of similar strings.

Usage

```
ClusterStrings(x, maxCluster = 12)
```

Arguments

x	Character vector.
maxCluster	Integer specifying maximum number of clusters to consider.

Value

NameClusters() returns an integer assigning each element of x to a cluster, with an attribute med specifying the median string in each cluster, and silhouette reporting the silhouette coefficient of the optimal clustering. Coefficients < 0.5 indicate weak structure, and no clusters are returned. If the number of unique elements of x is less than maxCluster, all occurrences of each entry are assigned to an individual cluster.

Other utility functions: [QuartetResolution\(\)](#), [WhenFirstHit\(\)](#)

Examples

```
ClusterStrings(c(paste0("FirstCluster ", 1:5),
                 paste0("SecondCluster.", 8:12),
                 paste0("AnotherCluster_", letters[1:6])))
```

ConcordantInformation *Evaluate the concordance of information between a tree and a dataset*

Description

Details the amount of information in a phylogenetic dataset that is consistent with a specified phylogenetic tree, and the signal:noise ratio of the character matrix implied if the tree is true.

Usage

```
ConcordantInformation(tree, dataset)
```

```
Evaluate(tree, dataset)
```

```
ConcordantInfo(tree, dataset)
```

Arguments

tree	A tree of class phylo .
dataset	A phylogenetic data matrix of phangorn class <code>phyDat</code> , whose names correspond to the labels of any accompanying tree. Perhaps load into R using ReadAsPhyDat . Additive (ordered) characters can be handled using Decompose .

Details

Presently restricted to datasets whose characters contain a maximum of two parsimony-informative states.

Value

`ConcordantInformation()` returns a named vector with elements:

- `informationContent`: cladistic information content of dataset
- `signal, noise`: amount of cladistic information that represents phylogenetic signal and noise, according to tree
- `signalToNoise`: the implied signal:noise ratio of dataset
- `treeInformation`: the cladistic information content of a bifurcating tree on dataset; this is the minimum amount of information necessary to resolve a bifurcating tree, assuming no duplicate information or noise
- `matrixToTree`: the ratio of the cladistic information content of the matrix to the cladistic information content of the tree, a measure of the redundancy of the matrix
- `ignored`: information content of characters whose signal and noise could not be calculated (too many states) and so are not included in the totals above.

Examples

```
data(congreveLamsdellMatrices)
myMatrix <- congreveLamsdellMatrices[[10]]
ConcordantInformation(TreeTools::NJTree(myMatrix), myMatrix)
```

congreveLamsdellMatrices
100 simulated data matrices

Description

Contains the 100 simulated matrices generated by (Congreve and Lamsdell 2016) using a heterogeneous Markov-k model, generated from the [referenceTree](#) topology, with all branches sharing an equal length.

Usage

```
congreveLamsdellMatrices
```

Format

A list with 100 entries, each comprising a phyDat object of 55 characters for 22 taxa

```

Consistency	<i>Consistency / retention "indices"</i>
-------------	--

Description

Consistency() calculates the consistency "index" and retention index (Farris 1989) for each character in a dataset, given a bifurcating tree. Although there is not a straightforward interpretation of these indices, they are sometimes taken as an indicator of the fit of a character to a tree. Values correlate with the number of species sampled and the distribution of taxa between character states, so are not strictly comparable between characters in which these factors differ; and values cannot be compared between datasets (Speed and Arbuckle 2017).

Usage

```
Consistency(dataset, tree, nRelabel = 0, compress = FALSE)
```

Arguments

dataset	A phylogenetic data matrix of phangorn class <code>phyDat</code> , whose names correspond to the labels of any accompanying tree. Perhaps load into R using ReadAsPhyDat . Additive (ordered) characters can be handled using Decompose .
tree	A tree of class phylo .
nRelabel	Integer specifying how many times to relabel leaves when estimating null tree length for RHI calculation. Steell et al. (2023) recommend 1000, but suggest that 100 may suffice. If zero (the default), the RHI is not calculated.
compress	Logical specifying whether to retain the compression of a <code>phyDat</code> object or to return a vector specifying to each individual character, decompressed using the dataset's index attribute.

Details

The **consistency "index"** (Kluge and Farris 1969) is defined as the number of steps observed in the most parsimonious mapping of a character to a tree, divided by the number of steps observed on the shortest possible tree for that character. A value of one indicates that a character's fit to the tree is optimal. Note that as the possible values of the consistency index do not range from zero to one, it is not an index in the mathematical sense of the term. Shortcomings of this measure are widely documented (Archie 1989-09; Brooks et al. 1986; Steell et al. 2023).

The maximum length of a character (see [MaximumLength\(\)](#)) is the number of steps in a parsimonious reconstruction on the longest possible tree for a character. The **retention index** is the maximum length of a character minus the number of steps observed on a given tree; divided by the maximum length minus the minimum length. It is interpreted as the ratio between the observed homoplasy, and the maximum observed homoplasy, and scales from zero (worst fit that can be reconstructed under parsimony) to one (perfect fit).

The **rescaled consistency index** is the product of the consistency and retention indices; it rescales the consistency index such that its range of possible values runs from zero (least consistent) to one (perfectly consistent).

The **relative homoplasy index** (Steell et al. 2023) is the ratio of the observed excess tree length to the excess tree length due to chance, taken as the median score of a character when the leaves of the given tree are randomly shuffled.

The lengths of characters including inapplicable tokens are calculated following Brazeau et al. (2019), matching their default treatment in `TreeLength()`.

Value

`Consistency()` returns a matrix with named columns specifying the consistency index (`ci`), retention index (`ri`), rescaled consistency index (`rc`) and relative homoplasy index (`rhi`).

dataset <- inapplicable.phyData[[4]]
head(Consistency(dataset, TreeTools::NJTree(dataset), nRelabel = 10))
```

cSPR	cSPR() <i>expects a tree rooted on a single tip.</i>
------	--

Description

cSPR() expects a tree rooted on a single tip.

Usage

```
cSPR(tree, whichMove = NULL)
```

Arguments

tree	A tree of class <code>phylo</code> .
whichMove	Integer specifying which SPR move index to perform.

Author(s)

Martin R. Smith (martin.smith@durham.ac.uk)

Examples

```
tree <- TreeTools::BalancedTree(8)

# Tree must be rooted on leaf
tree <- TreeTools::RootTree(tree, 1)

# Random rearrangement
cSPR(tree)

# Specific rearrangement
cSPR(tree, 9)
```

ExpectedLength	<i>Expected length</i>
----------------	------------------------

Description

For a given dataset and tree topology, `ExpectedLength()` estimates the length expected if the states of each character are shuffled randomly across the leaves.

Usage

```
ExpectedLength(dataset, tree, nRelabel = 1000, compress = FALSE)
```

Arguments

dataset	A phylogenetic data matrix of phangorn class <code>phyDat</code> , whose names correspond to the labels of any accompanying tree. Perhaps load into R using ReadAsPhyDat . Additive (ordered) characters can be handled using Decompose .
tree	A tree of class phylo .
nRelabel	Integer specifying how many times to relabel leaves when estimating null tree length for RHI calculation. Steell et al. (2023) recommend 1000, but suggest that 100 may suffice. If zero (the default), the RHI is not calculated.
compress	Logical specifying whether to retain the compression of a <code>phyDat</code> object or to return a vector specifying to each individual character, decompressed using the dataset's index attribute.

Value

`ExpectedLength()` returns a numeric vector stating the median length of each character in dataset on tree after `nRelabel` random relabelling of leaves.

GapHandler

Read how a Morphy Object handles the inapplicable token

Description

Gaps represented by the inapplicable token can be treated as "missing data", i.e. as equivalent to the ambiguous token `?`; as an extra state, equivalent to other states such as `0` or `1`; or as "inapplicable data" using the algorithm of Brazeau, Guillerme and Smith (2019).

Usage

```
GapHandler(morphyObj)
```

Arguments

`morphyObj` Object of class `morphy`, perhaps created with [PhyDat2Morphy\(\)](#).

Value

`GapHandler()` returns a character string stating how gaps are handled by `morphyObj`.

Author(s)

Martin R. Smith (martin.smith@durham.ac.uk)

```

inapplicable.datasets *Thirty datasets with inapplicable data*

Description

These are the datasets used to evaluate the behaviour of the inapplicable algorithm in Brazeau et al. (2019). The name of each item corresponds to the datasets listed below. Datasets are sorted into two subsets, each sorted alphabetically; the first subset comprise simpler datasets with faster processing times. `inapplicable.datasets` provide the data in the matrix format generated by [read.nexus.data\(\)](#); `inapplicable.phyData` are in phyDat format. `inapplicable.trees` lists for each dataset a sample of up to 50 trees obtained by tree search under each inapplicable treatment, named accordingly. `inapplicable.citations` is a named character vector specifying the source of each dataset.

Usage

```
inapplicable.datasets
inapplicable.phyData
inapplicable.trees
inapplicable.citations
```

Format

- An object of class `list` of length 30.
- An object of class `list` of length 30.
- An object of class `list` of length 31.
- An object of class `character` of length 30.

Examples

```
data("inapplicable.datasets", package = "TreeSearch")
names(inapplicable.datasets)
```

```
is.morphyPtr
```

```
Is an object a valid Morphy object?
```

Description

Is an object a valid Morphy object?

Usage

```
is.morphyPtr(morphyObj)
```

Arguments

morphyObj Object of class morphy, perhaps created with [PhyDat2Morphy\(\)](#).

Value

is.morphyPtr() returns TRUE if morphyObj is a valid morphy pointer, FALSE otherwise.

Author(s)

Martin R. Smith (martin.smith@durham.ac.uk)

IWScore

Calculate the parsimony score of a tree given a dataset

Description

TreeLength() uses the Morphy library (Brazeau et al. 2017) to calculate a parsimony score for a tree, handling inapplicable data according to the algorithm of Brazeau et al. (2019). Trees may be scored using equal weights, implied weights (Goloboff 1993), or profile parsimony (Faith and Trueman 2001).

Usage

```
IWScore(tree, dataset, concavity = 10L, ...)
```

```
TreeLength(tree, dataset, concavity = Inf)
```

```
## S3 method for class 'phylo'
```

```
TreeLength(tree, dataset, concavity = Inf)
```

```
## S3 method for class 'numeric'
```

```
TreeLength(tree, dataset, concavity = Inf)
```

```
## S3 method for class 'list'
```

```
TreeLength(tree, dataset, concavity = Inf)
```

```
## S3 method for class 'multiPhylo'
```

```
TreeLength(tree, dataset, concavity = Inf)
```

```
Fitch(tree, dataset)
```

Arguments

tree	A tree of class <code>phylo</code> , a list thereof (optionally of class <code>multiPhylo</code>), or an integer – in which case tree random trees will be uniformly sampled.
dataset	A phylogenetic data matrix of phangorn class <code>phyDat</code> , whose names correspond to the labels of any accompanying tree. Perhaps load into R using ReadAsPhyDat . Additive (ordered) characters can be handled using Decompose .
concavity	Determines the degree to which extra steps beyond the first are penalized. Specify a numeric value to use implied weighting (Goloboff 1993); <code>concavity</code> specifies k in $k / e + k$. A value of 10 is recommended; TNT sets a default of 3, but this is too low in some circumstances (Goloboff et al. 2018; Smith 2019). Better still explore the sensitivity of results under a range of concavity values, e.g. $k = 2^{(1:7)}$. Specify <code>Inf</code> to weight each additional step equally, (which underperforms step weighting approaches (Goloboff et al. 2008; Goloboff et al. 2018; Goloboff and Arias 2019; Smith 2019)). Specify <code>"profile"</code> to employ an approximation of profile parsimony (Faith and Trueman 2001).
...	unused; allows additional parameters specified within ... to be received by the function without throwing an error.

Value

`TreeLength()` returns a numeric vector containing the score for each tree in `tree`.

data("inapplicable.datasets")
tree <- TreeTools::BalancedTree(inapplicable.phyData[[1]])
TreeLength(tree, inapplicable.phyData[[1]])
TreeLength(tree, inapplicable.phyData[[1]], concavity = 10)
TreeLength(tree, inapplicable.phyData[[1]], concavity = "profile")
TreeLength(5, inapplicable.phyData[[1]])
```

Jackknife

Jackknife resampling

Description

Resample trees using Jackknife resampling, i.e. removing a subset of characters.

Usage

```
Jackknife(
  tree,
  dataset,
  resampleFreq = 2/3,
  InitializeData = PhyDat2Morphy,
  CleanupData = UnloadMorphy,
  TreeScorer = MorphyLength,
  EdgeSwapper = TBRSwap,
  jackIter = 5000L,
```

```

    searchIter = 4000L,
    searchHits = 42L,
    verbosity = 1L,
    ...
)

```

Arguments

tree	A fully-resolved starting tree in phylo format, with the desired outgroup. Edge lengths are not supported and will be removed.
dataset	a dataset in the format required by <code>TreeScorer()</code> .
resampleFreq	Double between 0 and 1 stating proportion of characters to resample.
InitializeData	Function that sets up data object to prepare for tree search. The function will be passed the dataset parameter. Its return value will be passed to <code>TreeScorer()</code> and <code>CleanUpData()</code> .
CleanUpData	Function to destroy data object on function exit. The function will be passed the value returned by <code>InitializeData()</code> .
TreeScorer	function to score a given tree. The function will be passed three parameters, corresponding to the parent and child entries of a tree's edge list, and a dataset.
EdgeSwapper	a function that rearranges a parent and child vector, and returns a list with modified vectors; for example SPRSwap() .
jackIter	Integer specifying number of jackknife iterations to conduct.
searchIter	Integer specifying maximum rearrangements to perform on each bootstrap or ratchet iteration. To override this value for a single swapper function, set e.g. <code>attr(SwapperFunction, "searchIter") <- 99</code>
searchHits	Integer specifying maximum times to hit best score before terminating a tree search within a ratchet iteration. To override this value for a single swapper function, set e.g. <code>attr(SwapperFunction, "searchHits") <- 99</code>
verbosity	Numeric specifying level of detail to display in console: larger numbers provide more verbose feedback to the user.
...	further parameters to send to <code>TreeScorer()</code>

Details

The function assumes that `InitializeData()` will return a morphy object; if this doesn't hold for you, post a [GitHub issue](#) or e-mail the maintainer.

Value

`Jackknife()` returns a list of trees recovered after jackknife iterations.

Author(s)

[Martin R. Smith](#) (martin.smith@durham.ac.uk)

JackLabels

*Label nodes with jackknife support values***Description**

[JackLabels\(\)](#) produces a list of node labels denoting split support from a set of resampled trees, optionally printing them on a tree.

Usage

```
JackLabels(
  tree,
  jackTrees,
  plot = TRUE,
  add = FALSE,
  adj = 0,
  col = NULL,
  frame = "none",
  pos = 2L,
  showFraction = FALSE,
  format = "character",
  ...
)
```

Arguments

<code>tree</code>	A tree of class phylo .
<code>jackTrees</code>	A list or <code>multiPhylo</code> object containing trees generated by Resample() or Jackknife() .
<code>plot</code>	Logical specifying whether to plot results; if <code>FALSE</code> , returns blank labels for nodes near the root that do not correspond to a unique split.
<code>add</code>	Logical specifying whether to add the labels to an existing plot.
<code>adj, col, frame, pos, ...</code>	Parameters to pass to nodeLabels() .
<code>showFraction</code>	Logical specifying whether to also annotate nodes with the fraction of replicates that were decisive for the split.
<code>format</code>	Character specifying return format. "character" returns a character string suitable to add to the <code>node.labels</code> attribute of a tree; "numeric" returns numeric values suitable for further analysis.

Details

If an element of `jackTrees` contains multiple trees, then the iteration is counted as supporting a split if all trees contain the split, and as contradicting the split if no trees contain it. If a split is only present in a subset of trees, that iteration is considered not to be decisive, and is ignored when calculating the support for that split.

Value

A named vector specifying the proportion of jackknife iterations consistent with each node in `tree`, as plotted. If `format = "character"`, blank entries are included corresponding to nodes that do not require labels, such that the return value is in the format required by `phylo$node.label`. If multiple trees are specified per iteration, the return value has an attribute `decisive` listing, for each entry in the return value, how many iterations were decisive for that split.

Other split support functions: [Jackknife\(\)](#), [MaximizeParsimony\(\)](#), [PresCont\(\)](#), [SiteConcordance](#)

Examples

```
library("TreeTools", quietly = TRUE) # for as.phylo

# jackTrees will usually be generated with Jackknife() or Resample(),
# but for simplicity:
jackTrees <- as.phylo(1:100, 8)

tree <- as.phylo(0, 8)
JackLabels(tree, jackTrees)

tree$node.label <- JackLabels(tree, jackTrees, plot = FALSE)

# Write the labelled tree to screen
ape::write.tree(tree)

# Write labelled trees to a nexus file:
# write.nexus(tree, file = filename)
```

LengthAdded *Contribution of character to leaf instability*

Description

Would tree lengths change if a character was coded as ambiguous for each leaf (Pol and Escapa 2009)?

Usage

```
LengthAdded(trees, char, concavity = Inf)
```

```
PolEscapa(trees, char, concavity = Inf)
```

Arguments

trees	List of trees of class phylo, or multiPhylo object.
char	phyDat object containing a single character.
concavity	Determines the degree to which extra steps beyond the first are penalized. Specify a numeric value to use implied weighting (Goloboff 1993); concavity specifies k in $k / e + k$. A value of 10 is recommended; TNT sets a default of 3, but this is too low in some circumstances (Goloboff et al. 2018; Smith 2019). Better still explore the sensitivity of results under a range of concavity values, e.g. $k = 2^{(1:7)}$. Specify Inf to weight each additional step equally, (which underperforms step weighting approaches (Goloboff et al. 2008; Goloboff et al. 2018; Goloboff and Arias 2019; Smith 2019)). Specify "profile" to employ an approximation of profile parsimony (Faith and Trueman 2001).

Details

High values for a leaf indicate that its coding contributes to instability ("wildcard" or "roguish" behaviour; see **Rogue** for further details). The coding is in tension with other data, which may indicate that the assumptions of homology that underlie the character's construction and scoring require careful scrutiny – or that the taxon in question has been subject to convergent evolution.

When inapplicable tokens are present in a character, the applicability of each coding is maintained: i.e. a leaf coded with an applicable token is never allowed to take an inapplicable value; and an inapplicable token remains inapplicable.

Value

LengthAdded() returns a named numeric vector listing the mean absolute change to tree length resulting if the character were coded ambiguous for each leaf in turn, under the specified concavity constant.

) -> XX # Suppress return value; display plot only
```

Description

Search for most parsimonious trees using the parsimony ratchet and TBR rearrangements, treating inapplicable data as such using the algorithm of Brazeau et al. (2019).

Tree search will be conducted from a specified or automatically-generated starting tree in order to find a tree with an optimal parsimony score, under implied or equal weights, treating inapplicable characters as such in order to avoid the artefacts of the standard Fitch algorithm (see Maddison 1993; Brazeau et al. 2019). Tree length is calculated using the MorphyLib C library (Brazeau et al. 2017).

Usage

```
MaximizeParsimony(  
  dataset,  
  tree,  
  ratchIter = 7L,  
  tbrIter = 2L,  
  startIter = 2L,  
  finalIter = 1L,  
  maxHits = NTip(dataset) * 1.8,  
  maxTime = 60,  
  quickHits = 1/3,  
  concavity = Inf,  
  ratchEW = TRUE,  
  tolerance = sqrt(.Machine[["double.eps"]]),  
  constraint,  
  verbosity = 3L  
)
```

```
Resample(  
  dataset,  
  tree,  
  method = "jack",  
  proportion = 2/3,  
  ratchIter = 1L,  
  tbrIter = 8L,  
  finalIter = 3L,  
  maxHits = 12L,  
  concavity = Inf,  
  tolerance = sqrt(.Machine[["double.eps"]]),  
  constraint,  
  verbosity = 2L,  
  ...  
)
```

```
EasyTrees()
```

```
EasyTreesy()
```

Arguments

dataset	A phylogenetic data matrix of phangorn class <code>phyDat</code> , whose names correspond to the labels of any accompanying tree. Perhaps load into R using ReadAsPhyDat . Additive (ordered) characters can be handled using Decompose .
tree	(optional) A bifurcating tree of class <code>phylo</code> , containing only the tips listed in <code>dataset</code> , from which the search should begin. If unspecified, an addition tree will be generated from <code>dataset</code> , respecting any supplied constraint. Edge lengths are not supported and will be deleted.
ratchetIter	Numeric specifying number of iterations of the parsimony ratchet (Nixon 1999) to conduct.
tbrIter	Numeric specifying the maximum number of TBR break points on a given tree to evaluate before terminating the search. One "iteration" comprises selecting a branch to break, and evaluating each possible reconnection point in turn until a new tree improves the score. If a better score is found, then the counter is reset to zero, and tree search continues from the improved tree.
startIter	Numeric: an initial round of tree search with <code>startIter</code> × <code>tbrIter</code> TBR break points is conducted in order to locate a local optimum before beginning ratchet searches.
finalIter	Numeric: a final round of tree search will evaluate <code>finalIter</code> × <code>tbrIter</code> TBR break points, in order to sample the final optimal neighbourhood more intensely.
maxHits	Numeric specifying the maximum times that an optimal parsimony score may be hit before concluding a ratchet iteration or final search concluded.
maxTime	Numeric: after <code>maxTime</code> minutes, stop tree search at the next opportunity.
quickHits	Numeric: iterations on subsampled datasets will retain <code>quickHits</code> × <code>maxHits</code> trees with the best score.
concavity	Determines the degree to which extra steps beyond the first are penalized. Specify a numeric value to use implied weighting (Goloboff 1993); <code>concavity</code> specifies k in $k / e + k$. A value of 10 is recommended; TNT sets a default of 3, but this is too low in some circumstances (Goloboff et al. 2018; Smith 2019). Better still explore the sensitivity of results under a range of concavity values, e.g. $k = 2^{(1:7)}$. Specify <code>Inf</code> to weight each additional step equally, (which underperforms step weighting approaches (Goloboff et al. 2008; Goloboff et al. 2018; Goloboff and Arias 2019; Smith 2019)). Specify "profile" to employ an approximation of profile parsimony (Faith and Trueman 2001).
ratchetEW	Logical specifying whether to use equal weighting during ratchet iterations, improving search speed whilst still facilitating escape from local optima.
tolerance	Numeric specifying degree of suboptimality to tolerate before rejecting a tree. The default, <code>sqrt(.Machine\$double.eps)</code> , retains trees that may be equally parsimonious but for rounding errors. Setting to larger values will include trees suboptimal by up to <code>tolerance</code> in search results, which may improve the accuracy of the consensus tree (at the expense of resolution) (Smith 2019).
constraint	Either an object of class <code>phyDat</code> , in which case returned trees will be perfectly compatible with each character in <code>constraint</code> ; or a tree of class <code>phylo</code> , all of whose nodes will occur in any output tree. See ImposeConstraint() and vignette for further examples.

verbosity	Integer specifying level of messaging; higher values give more detailed commentary on search progress. Set to 0 to run silently.
method	Unambiguous abbreviation of jackknife or bootstrap specifying how to re-sample characters. Note that jackknife is considered to give more meaningful results.
proportion	Numeric between 0 and 1 specifying what proportion of characters to retain under jackknife resampling.
...	Additional parameters to MaximizeParsimony().

Details

Tree search commences with `ratchIter` iterations of the parsimony ratchet (Nixon 1999), which bootstraps the input dataset in order to escape local optima. A final round of tree bisection and reconnection (TBR) is conducted to broaden the sampling of trees.

This function can be called using the R command line / terminal, or through the "shiny" graphical user interface app (type `EasyTrees()` to launch).

The optimal strategy for tree search depends in part on how close to optimal the starting tree is, the size of the search space (which increases super-exponentially with the number of leaves), and the complexity of the search space (e.g. the existence of multiple local optima).

One possible approach is to employ four phases:

1. Rapid search for local optimum: tree score is typically easy to improve early in a search, because the initial tree is often far from optimal. When many moves are likely to be accepted, running several rounds of search with a low value of `maxHits` and a high value of `tbrIter` allows many trees to be evaluated quickly, hopefully moving quickly to a more promising region of tree space.
2. Identification of local optimum: Once close to a local optimum, a more extensive search with a higher value of `maxHits` allows a region to be explored in more detail. Setting a high value of `tbrIter` will search a local neighbourhood more completely.
3. Search for nearby peaks: Ratchet iterations allow escape from local optima. Setting `ratchIter` to a high value searches the wider neighbourhood more extensively for other nearby peaks; `ratchEW = TRUE` accelerates these exploratory searches. Ratchet iterations can be ineffective when `maxHits` is too low for the search to escape its initial location.
4. Extensive search of final optimum. As with step 2, it may be valuable to fully explore the optimum that is found after ratchet searches to be sure that the locally optimal score has been obtained. Setting a high value of `finalIter` performs a thorough search that can give confidence that further searches would not find better (local) trees.

A search is unlikely to have found a global optimum if:

- Tree score continues to improve on the final iteration. If a local optimum has not yet been reached, it is unlikely that a global optimum has been reached. Try increasing `maxHits`.
- Successive ratchet iterations continue to improve tree scores. If a recent ratchet iteration improved the score, rather than finding a different region of tree space with the same optimal score, it is likely that still better global optima remain to be found. Try increasing `ratchIter` (more iterations give more chance for improvement) and `maxHits` (to get closer to the local optimum after each ratchet iteration).

- Optimal areas of tree space are only visited by a single ratchet iteration. (See vignette: [Exploring tree space](#).) If some areas of tree space are only found by one ratchet iteration, there may well be other, better areas that have not yet been visited. Try increasing `ratchIter`.

When continuing a tree search, it is usually best to start from an optimal tree found during the previous iteration - there is no need to start from scratch.

A more time consuming way of checking that a global optimum has been reached is to repeat a search with the same parameters multiple times, starting from a different, entirely random tree each time. If all searches obtain the same optimal tree score despite their different starting points, this score is likely to correspond to the global optimum.

For detailed documentation of the "TreeSearch" package, including full instructions for loading phylogenetic data into R and initiating and configuring tree search, see the [package documentation](#).

Value

`MaximizeParsimony()` returns a list of trees with class `multiPhylo`. This lists all trees found during each search step that are within `tolerance` of the optimal score, listed in the sequence that they were first visited, and named according to the step in which they were first found; it may contain more than `maxHits` elements. Note that the default search parameters may need to be increased in order for these trees to be the globally optimal trees; examine the messages printed during tree search to evaluate whether the optimal score has stabilized.

The return value has the attribute `firstHit`, a named integer vector listing the number of optimal trees visited for the first time in each stage of the tree search. Stages are named:

- `seed`: starting trees;
- `start`: Initial TBR search;
- `ratchN`: Ratchet iteration N;
- `final`: Final TBR search. The first tree hit for the first time in ratchet iteration three is named `ratch3_1`.

`Resample()` returns a `multiPhylo` object containing a list of trees obtained by tree search using a resampled version of `dataset`.

Resampling

Note that bootstrap support is a measure of the amount of data supporting a split, rather than the amount of confidence that should be afforded the grouping. "Bootstrap support of 100% is not enough, the tree must also be correct" (Phillips et al. 2004). See discussion in Egan (2006); Wagele et al. (2009); (Simmons and Freudenstein 2011); Kumar et al. (2012).

For a discussion of suitable search parameters in resampling estimates, see Muller (2005). The user should decide whether to start each resampling from the optimal tree (which may be quicker, but result in overestimated support values as searches get stuck in local optima close to the optimal tree) or a random tree (which may take longer as more rearrangements are necessary to find an optimal tree on each iteration).

For other ways to estimate clade concordance, see [SiteConcordance\(\)](#).

```

MinimumLength

Minimum and Maximum lengths possible for a character

Description

The smallest and largest length that a phylogenetic character can attain on any tree.

Usage

```
MinimumLength(x, compress = FALSE)
```

```
## S3 method for class 'phyDat'
```

```
MinimumLength(x, compress = FALSE)
```

```
## S3 method for class 'numeric'
MinimumLength(x, compress = NA)

## S3 method for class 'character'
MinimumLength(x, compress = TRUE)

## S3 method for class 'character'
MaximumLength(x, compress = TRUE)

MinimumSteps(x)

MaximumLength(x, compress = TRUE)

## S3 method for class 'numeric'
MaximumLength(x, compress = NA)
```

Arguments

x	An object of class <code>phyDat</code> ; or a string to be coerced to a <code>phyDat</code> object via <code>TreeTools::StringToPhyDat()</code> ; or an integer vector listing the tokens that may be present at each tip along a single character, with each token represented as a binary digit; e.g. a value of 11 ($= 2^0 + 2^1 + 2^3$) means that the tip may have tokens 0, 1 or 3. Inapplicable tokens should be denoted with the integer 0 (not 2^0).
compress	Logical specifying whether to retain the compression of a <code>phyDat</code> object or to return a vector specifying to each individual character, decompressed using the dataset's index attribute.

Details

Ambiguous inapplicable states (e.g. $\{0, -\}$) are currently replaced with the plain inapplicable token `-`, reflecting the current behaviour of Morphy.

Value

`MinimumLength()` returns a vector of integers specifying the minimum number of steps that each character must contain.

`MaximumLength()` returns a vector of integers specifying the maximum number of steps that each character can attain in a parsimonious reconstruction on a tree. Inapplicable tokens are not yet supported.

```

MorphyBootstrap

Parsimony Ratchet

Description

`Ratchet()` uses the parsimony ratchet (Nixon 1999) to search for a more parsimonious tree using custom optimality criteria.

Usage

```
MorphyBootstrap(
  edgeList,
  morphyObj,
  EdgeSwapper = NNISwap,
  maxIter,
  maxHits,
  verbosity = 1L,
  stopAtPeak = FALSE,
  stopAtPlateau = 0L,
  ...
)
```

```
Ratchet(  
  tree,  
  dataset,  
  InitializeData = PhyDat2Morphy,  
  CleanUpData = UnloadMorphy,  
  TreeScorer = MorphyLength,  
  Bootstrapper = MorphyBootstrap,  
  swappers = list(TBRSwap, SPRSwap, NNISwap),  
  BootstrapSwapper = if (is.list(swappers)) swappers[[length(swappers)]] else swappers,  
  returnAll = FALSE,  
  stopAtScore = NULL,  
  stopAtPeak = FALSE,  
  stopAtPlateau = 0L,  
  ratchIter = 100,  
  ratchHits = 10,  
  searchIter = 4000,  
  searchHits = 42,  
  bootstrapIter = searchIter,  
  bootstrapHits = searchHits,  
  verbosity = 1L,  
  suboptimal = sqrt(.Machine[["double.eps"]]),  
  ...  
)  
  
MultiRatchet(  
  tree,  
  dataset,  
  ratchHits = 10,  
  searchIter = 500,  
  searchHits = 20,  
  verbosity = 0L,  
  swappers = list(RootedNNISwap),  
  nSearch = 10,  
  stopAtScore = NULL,  
  ...  
)  
  
RatchetConsensus(  
  tree,  
  dataset,  
  ratchHits = 10,  
  searchIter = 500,  
  searchHits = 20,  
  verbosity = 0L,  
  swappers = list(RootedNNISwap),  
  nSearch = 10,  
  stopAtScore = NULL,  
  ...  
)
```

)

Arguments

edgeList	a list containing the following: <ul style="list-style-type: none"> • vector of integers corresponding to the parent of each edge in turn • vector of integers corresponding to the child of each edge in turn • (optionally) score of the tree • (optionally, if score provided) number of times this score has been hit
morphObj	Object of class morphy, perhaps created with PhyDat2Morphy() .
EdgeSwapper	a function that rearranges a parent and child vector, and returns a list with modified vectors; for example SPRSwap() .
maxIter	Numeric specifying maximum number of iterations to perform in tree search.
maxHits	Numeric specifying maximum number of hits to accomplish in tree search.
verbosity	Numeric specifying level of detail to display in console: larger numbers provide more verbose feedback to the user.
stopAtPeak	Logical specifying whether to terminate search once a subsequent iteration recovers a sub-optimal score. Will be overridden if a passed function has an attribute stopAtPeak set by <code>attr(FunctionName, "stopAtPeak") <- TRUE</code> .
stopAtPlateau	Integer. If > 0, tree search will terminate if the score has not improved after stopAtPlateau iterations. Will be overridden if a passed function has an attribute stopAtPlateau set by <code>attr(FunctionName, "stopAtPlateau") <- TRUE</code> .
...	further parameters to send to TreeScorer()
tree	A fully-resolved starting tree in phylo format, with the desired outgroup. Edge lengths are not supported and will be removed.
dataset	a dataset in the format required by TreeScorer() .
InitializeData	Function that sets up data object to prepare for tree search. The function will be passed the dataset parameter. Its return value will be passed to TreeScorer() and CleanUpData() .
CleanUpData	Function to destroy data object on function exit. The function will be passed the value returned by InitializeData() .
TreeScorer	function to score a given tree. The function will be passed three parameters, corresponding to the parent and child entries of a tree's edge list, and a dataset.
Bootstrapper	Function to perform bootstrapped rearrangements of tree. First arguments will be an edgeList and a dataset, initialized using InitializeData() . Should return a rearranged edgeList.
swappers	A list of functions to use to conduct edge rearrangement during tree search. Provide functions like NNISwap to shuffle root position, or RootedTBRSwap if the position of the root should be retained. You may wish to use extreme swappers (such as TBR) early in the list, and a more subtle rearranger (such as NNI) later in the list to make incremental tinkering once an almost-optimal tree has been found.

BootstrapSwapper	Function such as RootedNNISwap to use to rearrange trees within <code>Bootstrapper()</code> .
returnAll	Set to TRUE to report all MPTs encountered during the search, perhaps to analyse consensus.
stopAtScore	stop search as soon as this score is hit or beaten.
ratchIter	Stop when this many ratchet iterations have been performed.
ratchHits	Stop when this many ratchet iterations have found the same best score.
searchIter	Integer specifying maximum rearrangements to perform on each bootstrap or ratchet iteration. To override this value for a single swapper function, set e.g. <code>attr(SwapperFunction, "searchIter") <- 99</code>
searchHits	Integer specifying maximum times to hit best score before terminating a tree search within a ratchet iteration. To override this value for a single swapper function, set e.g. <code>attr(SwapperFunction, "searchHits") <- 99</code>
bootstrapIter	Integer specifying maximum rearrangements to perform on each bootstrap iteration (default: <code>searchIter</code>).
bootstrapHits	Integer specifying maximum times to hit best score on each bootstrap iteration (default: <code>searchHits</code>).
suboptimal	retain trees that are suboptimal by this score. Defaults to a small value that will counter rounding errors.
nSearch	Number of Ratchet searches to conduct (for <code>RatchetConsensus()</code>)

Details

For usage pointers, see the [vignette](#).

Value

`MorphyBootstrap()` returns a tree that is optimal under a random sampling of the original characters.

`Ratchet()` returns a tree modified by parsimony ratchet iterations.

`MultiRatchet()` returns a list of optimal trees produced by `nSearch` `Ratchet()` searches, from which a consensus tree can be generated using `ape::consensus()` or `TreeTools::ConsensusWithout()`.

Functions

- `RatchetConsensus()`: deprecated alias for `MultiRatchet()`

Examples

```
data("Lobo", package = "TreeTools")
njtree <- TreeTools::NJTree(Lobo.phy)
# Increase value of ratchetIter and searchHits to do a proper search
quickResult <- Ratchet(njtree, Lobo.phy, ratchetIter = 2, searchHits = 3)

# Plot result (legibly)
oldPar <- par(mar = rep(0, 4), cex = 0.75)
plot(quickResult)
par(oldPar)
```

MorphyWeights

Set and get the character weightings associated with a Morphy object.

Description

`MorphyWeights()` details the approximate and exact weights associated with characters in a Morphy object; `SetMorphyWeights()` edits them.

Usage

```
MorphyWeights(morphyObj)
```

```
SetMorphyWeights(weight, morphyObj, checkInput = TRUE)
```

Arguments

<code>morphyObj</code>	Object of class <code>morphy</code> , perhaps created with <code>PhyDat2Morphy()</code> .
<code>weight</code>	A vector listing the new weights to be applied to each character
<code>checkInput</code>	Whether to sanity-check input data before applying. Defaults to <code>TRUE</code> to protect the user from crashes.

Value

`MorphyWeights()` returns a data frame with two named rows and one column per character pattern: row 1, `approx`, is a list of integers specifying the approximate (integral) weights used by `MorphyLib`; row 2, `exact`, is a list of numerics specifying the exact weights specified by the user.

`SetMorphyWeights()` returns the Morphy error code generated when applying weight.

MostContradictedFreq *Frequency of most common contradictory split*

Description

`MostContradictedFreq()` counts the occurrences of the single split that most frequently contradicts each split in tree.

This function was written during a code sprint: its documentation and test cases have not yet been carefully scrutinized, and its implementation may change without notice. Please alert the maintainer to any issues you encounter.

Usage

```
MostContradictedFreq(tree, forest)
```

Arguments

<code>tree</code>	A tree of class phylo .
<code>forest</code>	a list of trees of class <code>phylo</code> , or a <code>multiPhylo</code> object; or a <code>Splits</code> object.

Details

Goloboff et al. (2003) propose comparing the frequency of a split in a resampled population with the frequency of the most common contradictory split. This measure contributes to the "groups present / contradicted" score.

Value

MostContradictedFreq() returns, for each split in tree, the number of times that its most common contradictory split occurs in forest.

See Also

PresCont() calculates the "groups present / contradicted" score.

 NNI

Nearest neighbour interchange (NNI)

Description

NNI() performs a single iteration of the nearest-neighbour interchange algorithm; RootedNNI() retains the position of the root. These functions are based on equivalents in the **phangorn** package. cNNI() is an equivalent function coded in C, that runs much faster.

Usage

```
NNI(tree, edgeToBreak = NULL)
```

```
cNNI(tree, edgeToBreak = NULL, whichSwitch = NULL)
```

```
NNISwap(parent, child, nTips = (length(parent)/2L) + 1L, edgeToBreak = NULL)
```

```
RootedNNI(tree, edgeToBreak = NULL)
```

```
RootedNNISwap(
  parent,
  child,
  nTips = (length(parent)/2L) + 1L,
  edgeToBreak = NULL
)
```

Arguments

tree	A tree of class <code>phylo</code> . For <code>cNNI()</code> , this must be a binary tree rooted on a single leaf, whose root node is the lowest numbered internal node.
edgeToBreak	In <code>(Rooted/Double)NNI()</code> , an optional integer specifying the index of an edge to rearrange, generated randomly if not specified. If <code>-1</code> , a complete list of all trees one step from the input tree will be returned. In <code>cNNI()</code> , an integer from zero to <code>nEdge(tree) - nTip(tree) - 2</code> , specifying which internal edge to break.
whichSwitch	Integer from zero to one, specifying which way to re-build the broken internal edge.
parent	Integer vector corresponding to the first column of the edge matrix of a tree of class <code>phylo</code> , i.e. <code>tree[["edge"]][, 1]</code>

child	Integer vector corresponding to the second column of the edge matrix of a tree of class <code>phylo</code> , i.e. <code>tree[["edge"]][, 2]</code> .
nTips	(optional) Number of tips.

Details

Branch lengths are not supported.

All nodes in a tree must be bifurcating; `ape::collapse.singles()` and `ape::multi2di()` may help.

Value

Returns a tree with class `phylo` (if `returnAll = FALSE`) or a set of trees, with class `multiPhylo` (if `returnAll = TRUE`).

`cNNI()` returns a tree of class `phylo`, rooted on the same leaf, on which the specified rearrangement has been conducted.

`NNISwap()` returns a list containing two elements, corresponding in turn to the rearranged parent and child parameters.

a list containing two elements, corresponding in turn to the rearranged parent and child parameters

Functions

- `NNISwap()`: faster version that takes and returns parent and child parameters
- `RootedNNI()`: Perform NNI rearrangement, retaining position of root
- `RootedNNISwap()`: faster version that takes and returns parent and child parameters

Author(s)

Martin R. Smith (martin.smith@durham.ac.uk)

References

The algorithm is summarized in Felsenstein J (2004). *Inferring phylogenies*. Sinauer Associates, Sunderland, Massachusetts.

See Also

Other tree rearrangement functions: `SPR()`, `TBR()`

Examples

```
tree <- TreeTools::BalancedTree(8)
# A random rearrangement
NNI(tree)
cNNI(tree)

# All trees one NNI rearrangement away
NNI(tree, edgeToBreak = -1)
```

```
# Manual random sampling
cNNI(tree, sample.int(14 - 8 - 1, 1), sample.int(2, 1))

# A specified rearrangement
cNNI(tree, 0, 0)

# If a tree may not be binary, collapse nodes with
tree <- TreeTools::MakeTreeBinary(tree)

# If a tree may be improperly rooted, use
tree <- TreeTools::RootTree(tree, 1)

# If a tree may exhibit unusual node ordering, this can be addressed with
tree <- TreeTools::Preorder(tree)
```

PhyDat2Morphy	<i>Initialize a Morphy object from a phyDat object</i>
---------------	--

Description

Creates a new Morphy object with the same size and characters as the phyDat object. Once finished with the object, it should be destroyed using `UnloadMorphy()` to free the allocated memory.

Usage

```
PhyDat2Morphy(phy, gap = "inapplicable", weight = attr(phy, "weight"))
```

Arguments

phy	An object of phangorn class phyDat.
gap	An unambiguous abbreviation of inapplicable, ambiguous (= missing), or extra state, specifying how gaps will be handled.
weight	Numeric giving weight to apply to each character. Will be recycled.

Value

PhyDat2Morphy() returns a pointer to an initialized Morphy object.

Author(s)

Martin R. Smith (martin.smith@durham.ac.uk)

See Also

Examples

```
data("Lobo", package="TreeTools")
morphyObj <- PhyDat2Morphy(Lobo.phy)
# Set object to be destroyed at end of session or closure of function
# on.exit(morphyObj <- UnloadMorphy(morphyObj), add = TRUE)

# Do something with pointer
# ....

# Or, instead of on.exit, manually destroy morphy object and free memory:
morphyObj <- UnloadMorphy(morphyObj)
```

PlotCharacter

Plot the distribution of a character on a tree

Description

Reconstructs the distribution of a character on a tree topology using the modified Fitch algorithm presented in Brazeau et al. (2019).

Usage

```
PlotCharacter(
  tree,
  dataset,
  char = 1L,
  updateTips = FALSE,
  plot = TRUE,
  tokenCol = NULL,
  ambigCol = "grey",
  inappCol = "lightgrey",
  ambigLty = "dotted",
  inappLty = "dashed",
  plainLty = par("lty"),
  tipOffset = 1,
  unitEdge = FALSE,
  Display = function(tree) tree,
```

```
    ...
  )

## S3 method for class 'phylo'
PlotCharacter(
  tree,
  dataset,
  char = 1L,
  updateTips = FALSE,
  plot = TRUE,
  tokenCol = NULL,
  ambigCol = "grey",
  inappCol = "lightgrey",
  ambigLty = "dotted",
  inappLty = "dashed",
  plainLty = par("lty"),
  tipOffset = 1,
  unitEdge = FALSE,
  Display = function(tree) tree,
  ...
)

## S3 method for class 'multiPhylo'
PlotCharacter(
  tree,
  dataset,
  char = 1L,
  updateTips = FALSE,
  plot = TRUE,
  tokenCol = NULL,
  ambigCol = "grey",
  inappCol = "lightgrey",
  ambigLty = "dotted",
  inappLty = "dashed",
  plainLty = par("lty"),
  tipOffset = 1,
  unitEdge = FALSE,
  Display = function(tree) tree,
  ...
)

## S3 method for class 'list'
PlotCharacter(
  tree,
  dataset,
  char = 1L,
  updateTips = FALSE,
  plot = TRUE,
```

```

tokenCol = NULL,
ambigCol = "grey",
inappCol = "lightgrey",
ambigLty = "dotted",
inappLty = "dashed",
plainLty = par("lty"),
tipOffset = 1,
unitEdge = FALSE,
Display = function(tree) tree,
...
)

```

Arguments

tree	A bifurcating tree of class <code>phylo</code> , or a list or <code>multiPhylo</code> object containing such trees.
dataset	A phylogenetic data matrix of phangorn class <code>phyDat</code> , whose names correspond to the labels of any accompanying tree. Perhaps load into R using ReadAsPhyDat . Additive (ordered) characters can be handled using Decompose .
char	Index of character to plot.
updateTips	Logical; if FALSE, tips will be labelled with their original state in dataset.
plot	Logical specifying whether to plot the output.
tokenCol	Palette specifying colours to associate with each token in turn, in the sequence listed in <code>attr(dataset, "levels")</code> .
ambigCol, ambigLty, inappCol, inappLty, plainLty	Colours and line types to apply to ambiguous, inapplicable and applicable tokens. See the lty graphical parameter for details of line styles. Overrides <code>tokenCol</code> .
tipOffset	Numeric: how much to offset tips from their labels.
unitEdge	Logical: Should all edges be plotted with a unit length?
Display	Function that takes argument <code>tree</code> and returns a tree of class <code>phylo</code> , formatted as it will be plotted.
...	Further arguments to pass to <code>plot.phylo()</code> .

Value

`PlotCharacter()` invisibly returns a matrix in which each row corresponds to a numbered tip or node of tree, and each column corresponds to a token; the tokens that might parsimoniously be present at each point on a tree are denoted with TRUE. If multiple trees are supplied, the strict consensus of all trees and reconstructions will be returned; i.e. if a node is reconstructed as `0` in one tree, and `2` in another, it will be labelled `(02)`.

Examples

```
# Set up plotting area
oPar <- par(mar = rep(0, 4))

tree <- ape::read.tree(text =
  "((((((a, b), c), d), e), f), (g, (h, (i, (j, (k, l))))));")
## A character with inapplicable data
dataset <- TreeTools::StringToPhyDat("23--1??--032", tips = tree)
plotted <- PlotCharacter(tree, dataset)
plotted

# Character from a real dataset
data("Lobo", package = "TreeTools")
dataset <- Lobo.phy
tree <- TreeTools::NJTree(dataset)
PlotCharacter(tree, dataset, 14)
par(oPar)
```

PrepareDataProfile *Prepare data for Profile Parsimony*

Description

Calculates profiles for each character in a dataset. Will also simplify characters, with a warning, where they are too complex for the present implementation of profile parsimony:

- inapplicable tokens will be replaced with the ambiguous token (i.e. - → ?);
- Ambiguous tokens will be treated as fully ambiguous (i.e. {02} → ?)
- Where more than two states are informative (i.e. unambiguously present in more than one taxon), states beyond the two most informative will be ignored.

Usage

```
PrepareDataProfile(dataset)
```

```
PrepareDataIW(dataset)
```

Arguments

dataset dataset of class phyDat

Value

An object of class `phyDat`, with additional attributes. `PrepareDataProfile` adds the attributes:

- `info.amounts`: details the information represented by each character when subject to N additional steps.
- `informative`: logical specifying which characters contain any phylogenetic information.
- `bootstrap`: The character vector `c("info.amounts", "split.sizes")`, indicating attributes to sample when bootstrapping the dataset (e.g. in Ratchet searches).

`PrepareDataIW` adds the attribute:

- `min.length`: The minimum number of steps that must be present in each transformation series.

Functions

- `PrepareDataIW()`: Prepare data for implied weighting

dataset <- congreveLamsdellMatrices[[42]]
PrepareDataProfile(dataset)
```

PresCont

Group present or contradicted score

Description

Implements the Groups Present / Contradicted (GC) measure (Goloboff et al. 2003).

This function was written during a code sprint: its documentation and test cases have not yet been carefully scrutinized, and its implementation may change without notice. Please alert the maintainer to any issues you encounter.

Usage

```

PresCont(
  tree,
  forest,
  plot = TRUE,
  add = FALSE,
  adj = 0,
  col = NULL,
  frame = "none",
  pos = 2L,
  ...
)

```

Arguments

tree	A tree of class <code>phylo</code> .
forest	a list of trees of class <code>phylo</code> , or a <code>multiPhylo</code> object; or a <code>Splits</code> object.
plot	Logical specifying whether to plot results; if <code>FALSE</code> , returns blank labels for nodes near the root that do not correspond to a unique split.
add	Logical specifying whether to add the labels to an existing plot.
adj, col, frame, pos, ...	Parameters to pass to <code>nodeLabels()</code> .

Details

The GC score ranges from -1 to 1, and is intended as an alternative to bootstrap or jackknife support values.

The GC score counts the number of trees in `forest` that include a given split, and subtracts the number of times that the *most frequent* contradictory split occurs. This value is then divided by the number of trees in `forest`.

A score of 1 denotes that every tree in a forest (typically of bootstrap or jackknife replicates) contains the split in question. A score of -1 denotes that a specific contradictory split occurs in every tree in forest. A score of zero indicates no support: i.e. that the split exhibits no more support than its most common contradictory split.

The most frequent contradictory split is used to discriminate between a scenario where a given split enjoys much more support than any other alternative (even if many alternatives exist, each with low support), and a scenario where the chosen split is scarcely any better supported than a competing alternative. The split is considered better supported than the latter, where the runner-up may become preferred with a modest change to the underlying dataset.

Value

`PresCont()` returns a character vector that labels the nodes in `tree` in sequence, suitable for passing to `nodeLabels()` or `tree$node.label`. If `plot = TRUE`, it also plots `tree`, with splits labelled by their groups present / contradicted score.

[SplitFrequency\(\)](#) and [MostContradictedFreq\(\)](#) will compute the number of trees that contain the split, and the frequency of the most contradicted split, respectively.

Other split support functions: [JackLabels\(\)](#), [Jackknife\(\)](#), [MaximizeParsimony\(\)](#), [SiteConcordance](#)

Examples

```
library("TreeTools", quietly = TRUE) # for as.phylo

# jackTrees will usually be generated with Jackknife() or Resample(),
# but for simplicity:
jackTrees <- as.phylo(1:100, 8)

tree <- as.phylo(0, 8)
PresCont(tree, jackTrees)

tree$node.label <- PresCont(tree, jackTrees, plot = FALSE)

# Write the labelled tree to screen
ape::write.tree(tree)

# Write labelled trees to a nexus file:
# write.nexus(tree, file = filename)

# Compute the measure for further analysis
gpc <- (SplitFrequency(tree, jackTrees) -
  MostContradictedFreq(tree, jackTrees)) / length(jackTrees)
gpc
```

profiles

Empirically counted profiles for small trees

Description

The base 2 logarithm of the number of trees containing s steps, calculated by scoring a character on each n -leaf tree.

Usage

```
profiles
```

Format

A list with the structure `profiles[[number of leaves]][[number of tokens]][[tokens in smallest split]]`. The list entry returns a named numeric vector; each entry lists \log_2 (proportion of n -leaf trees with s or fewer steps for this character).

See Also

Other profile parsimony functions: [Carter1\(\)](#), [PrepareDataProfile\(\)](#), [StepInformation\(\)](#), [WithOneExtraStep\(\)](#)

Examples

```
data(profiles)

# Load profile for a character of the structure 0 0 0 1 1 1 1 1
profile3.5 <- profiles[[8]][[2]][[3]]

# Number of trees with _s_ or fewer steps on that character
TreeTools::NUnrooted(8) * 2 ^ profile3.5
```

QuartetResolution *Relationship between four taxa*

Description

Relationship between four taxa

Usage

```
QuartetResolution(trees, tips)
```

Arguments

<code>trees</code>	A list of trees of class <code>phylo</code> , or a <code>multiPhylo</code> object.
<code>tips</code>	Vector specifying four tips whose relationship should be reported, in a format accepted by KeepTip() .

Value

A vector specifying an integer, for each tree, which of `tips[-1]` is most closely related to `tips[1]`.

See Also

Other utility functions: [ClusterStrings\(\)](#), [WhenFirstHit\(\)](#)

Examples

```
trees <- inapplicable.trees[["Vinther2008"]]
tips <- c("Lingula", "Halkieria", "Wiwaxia", "Acaenoplax")
QuartetResolution(trees, tips)
```

RandomMorphyTree	<i>Random postorder tree</i>
------------------	------------------------------

Description

Random postorder tree

Usage

```
RandomMorphyTree(nTip)
```

Arguments

nTip Integer specifying the number of tips to include in the tree (minimum 2).

Value

A list with three elements, each a vector of integers, respectively containing:

- The parent of each tip and node, in order
- The left child of each node
- The right child of each node.

See Also

Other tree generation functions: [AdditionTree\(\)](#)

RandomTreeScore	<i>Parsimony score of random postorder tree</i>
-----------------	---

Description

Parsimony score of random postorder tree

Usage

```
RandomTreeScore(morphyObj)
```

Arguments

morphyObj Object of class morphy, perhaps created with [PhyDat2Morphy\(\)](#).

Value

RandomTreeScore() returns the parsimony score of a random tree for the given Morphy object.

Examples

```
tokens <- matrix(c(
  0, "-", "-", 1, 1, 2,
  0, 1, 0, 1, 2, 2,
  0, "-", "-", 0, 0, 0), byrow = TRUE, nrow = 3L,
  dimnames = list(letters[1:3], NULL))
pd <- TreeTools::MatrixToPhyDat(tokens)
morphyObj <- PhyDat2Morphy(pd)

RandomTreeScore(morphyObj)

morphyObj <- UnloadMorphy(morphyObj)
```

RearrangeEdges

Rearrange edges of a phylogenetic tree

Description

RearrangeEdges() performs the specified edge rearrangement on a matrix that corresponds to the edges of a phylogenetic tree, returning the score of the new tree. Will generally be called from within a tree search function.

Usage

```
RearrangeEdges(
  parent,
  child,
  dataset,
  TreeScorer = MorphyLength,
  EdgeSwapper,
  scoreToBeat = TreeScorer(parent, child, dataset, ...),
  iter = "?",
  hits = 0L,
  verbosity = 0L,
  ...
)
```

Arguments

parent	Integer vector corresponding to the first column of the edge matrix of a tree of class <code>phylo</code> , i.e. <code>tree[["edge"]][, 1]</code>
child	Integer vector corresponding to the second column of the edge matrix of a tree of class <code>phylo</code> , i.e. <code>tree[["edge"]][, 2]</code> .

dataset	Third argument to pass to TreeScorer.
TreeScorer	function to score a given tree. The function will be passed three parameters, corresponding to the parent and child entries of a tree's edge list, and a dataset.
EdgeSwapper	a function that rearranges a parent and child vector, and returns a list with modified vectors; for example SPRSwap() .
scoreToBeat	Double giving score of input tree.
iter	iteration number of calling function, for reporting to user only.
hits	Integer giving number of times the input tree has already been hit.
verbosity	Numeric specifying level of detail to display in console: larger numbers provide more verbose feedback to the user.
...	further arguments to pass to TreeScorer(), e.g. dataset = .

Details

RearrangeTree() performs one tree rearrangement of a specified type, and returns the score of the tree (with the given dataset). It also reports the number of times that this score was hit in the current function call.

Value

This function returns a list with two to four elements, corresponding to a binary tree: - 1. Integer vector listing the parent node of each edge; - 2. Integer vector listing the child node of each edge; - 3. Score of the tree; - 4. Number of times that score has been hit.

data(referenceTree)
plot(referenceTree)
```

SingleCharMorph	<i>Morph object from single character</i>
-----------------	---

Description

Morph object from single character

Usage

```
SingleCharMorph(char, gap = "inapp")
```

Arguments

char	State of each character at each tip in turn, in a format that will be converted to a character string by <code>paste0(char, ";", collapse="")</code> .
gap	An unambiguous abbreviation of inapplicable, ambiguous (= missing), or extra state, specifying how gaps will be handled.

Value

A pointer to an object of class `morphyObj`. Don't forget to unload it when you've finished with it.

morphyObj <- UnloadMorphy(morphyObj)
```

SiteConcordance

Calculate site concordance factor

Description

The site concordance factor (Minh et al. 2020) is a measure of the strength of support that the dataset presents for a given split in a tree.

Usage

```
QuartetConcordance(tree, dataset = NULL, weight = TRUE)
```

```
ClusteringConcordance(tree, dataset)
```

```
PhylogeneticConcordance(tree, dataset)
```

```
MutualClusteringConcordance(tree, dataset)
```

```
SharedPhylogeneticConcordance(tree, dataset)
```

Arguments

tree	A tree of class phylo .
dataset	A phylogenetic data matrix of phangorn class <code>phyDat</code> , whose names correspond to the labels of any accompanying tree. Perhaps load into R using ReadAsPhyDat . Additive (ordered) characters can be handled using Decompose .
weight	Logical specifying whether to weight sites according to the number of quartets they are decisive for.

Details

`QuartetConcordance()` is the proportion of quartets (sets of four leaves) that are decisive for a split which are also concordant with it. For example, a quartet with the characters 0 0 0 1 is not decisive, as all relationships between those leaves are equally parsimonious. But a quartet with characters 0 0 1 1 is decisive, and is concordant with any tree that groups the first two leaves together to the exclusion of the second.

By default, the reported value weights each site by the number of quartets it is decisive for. This value can be interpreted as the proportion of all decisive quartets that are concordant with a split. If `weight = FALSE`, the reported value is the mean of the concordance value for each site. Consider a split associated with two sites: one that is concordant with 25% of 96 decisive quartets, and a second that is concordant with 75% of 4 decisive quartets. If `weight = TRUE`, the split concordance will be $24 + 3 / 96 + 4 = 27\%$. If `weight = FALSE`, the split concordance will be $\text{mean}(75\%, 25\%) = 50\%$.

`QuartetConcordance()` is computed exactly, using all quartets, where as other implementations (e.g. IQ-TREE) follow Minh2020) in using a random subsample of quartets for a faster, if potentially less accurate, computation.

NOTE: These functions are under development. They are incompletely tested, and may change without notice. Complete documentation and discussion will follow in due course.

# The contents of tree$node.label will be written at each node
tree$node.label <- labels[whichNode]

ape::write.tree(tree) # or write.nexus(tree, file = "mytree.nex")

# Display correlation between concordance factors
pairs(cbind(qc, cc, pc, spc, mcc), asp = 1)

```

 SPR

Subtree pruning and rearrangement (SPR)

Description

Perform one SPR rearrangement on a tree

Usage

```

SPR(tree, edgeToBreak = NULL, mergeEdge = NULL)

SPRMoves(tree, edgeToBreak = integer(0))

## S3 method for class 'phylo'
SPRMoves(tree, edgeToBreak = integer(0))

## S3 method for class 'matrix'
SPRMoves(tree, edgeToBreak = integer(0))

```

```

SPRSwap(
  parent,
  child,
  nEdge = length(parent),
  nNode = nEdge/2L,
  edgeToBreak = NULL,
  mergeEdge = NULL
)

RootedSPR(tree, edgeToBreak = NULL, mergeEdge = NULL)

RootedSPRSwap(
  parent,
  child,
  nEdge = length(parent),
  nNode = nEdge/2L,
  edgeToBreak = NULL,
  mergeEdge = NULL
)

```

Arguments

tree	A bifurcating tree of class <code>phylo</code> , with all nodes resolved;
edgeToBreak	the index of an edge to bisect, generated randomly if not specified.
mergeEdge	the index of an edge on which to merge the broken edge.
parent	Integer vector corresponding to the first column of the edge matrix of a tree of class <code>phylo</code> , i.e. <code>tree[["edge"]][, 1]</code>
child	Integer vector corresponding to the second column of the edge matrix of a tree of class <code>phylo</code> , i.e. <code>tree[["edge"]][, 2]</code> .
nEdge	(optional) integer specifying the number of edges of a tree of class <code>phylo</code> , i.e. <code>dim(tree\$edge)[1]</code>
nNode	(optional) Number of nodes.

Details

Equivalent to `kSPR()` in the **phangorn** package, but faster. Note that rearrangements that only change the position of the root WILL be returned by SPR. If the position of the root is irrelevant (as in Fitch parsimony, for example) then this function will occasionally return a functionally equivalent topology. `RootIrrelevantSPR` will search tree space more efficiently in these cases. Branch lengths are not (yet) supported.

All nodes in a tree must be bifurcating; `ape::collapse.singles` and `ape::multi2di` may help.

Value

This function returns a tree in `phyDat` format that has undergone one SPR iteration.

`TBRMoves()` returns a list of all trees one SPR move away from `tree`, with edges and nodes in preorder, rooted on the first-labelled tip.

a list containing two elements, corresponding in turn to the rearranged parent and child parameters
 a list containing two elements, corresponding in turn to the rearranged parent and child parameters

Functions

- `SPRSwap()`: faster version that takes and returns parent and child parameters
- `RootedSPR()`: Perform SPR rearrangement, retaining position of root
- `RootedSPRSwap()`: faster version that takes and returns parent and child parameters

Author(s)

Martin R. Smith

References

The SPR algorithm is summarized in Felsenstein J (2004). *Inferring phylogenies*. Sinauer Associates, Sunderland, Massachusetts.

See Also

- [RootedSPR\(\)](#): useful when the position of the root node should be retained.

Examples

```
{
tree <- ape::rtree(20, br=FALSE)
SPR(tree)
}
```

StepInformation

Information content of a character known to contain e steps

Description

`StepInformation()` calculates the phylogenetic information content of a character `char` when e extra steps are present, for all possible values of e .

Usage

```
StepInformation(char, ambiguousTokens = c("-", "?"))
```

Arguments

`char` Vector of tokens listing states for the character in question.
`ambiguousTokens` Vector specifying which tokens, if any, correspond to the ambiguous token (?).

Details

Calculates the number of trees consistent with the character having e extra steps, where e ranges from its minimum possible value (i.e. number of different tokens minus one) to its maximum.

Value

StepInformation() returns a numeric vector detailing the amount of phylogenetic information (in bits) associated with the character when 0, 1, 2... extra steps are present. The vector is named with the total number of steps associated with each entry in the vector: for example, a character with three observed tokens must exhibit two steps, so the first entry (zero extra steps) is named 2 (two steps observed).

Examples

```
character <- rep(c(0:3, "?", "-"), c(8, 5, 1, 1, 2, 2))
StepInformation(character)
```

summary.morphyPtr

Details the attributes of a morphy object

Description

Details the attributes of a morphy object

Usage

```
## S3 method for class 'morphyPtr'
summary(object, ...)
```

Arguments

object	A Morphy object
...	any other parameters...

Value

A list detailing the number of taxa, internal nodes, and characters and their weights.

Author(s)

Martin R. Smith (martin.smith@durham.ac.uk)

TaxonInfluence	<i>Rank taxa by their influence on phylogenetic results</i>
----------------	---

Description

TaxonInfluence() ranks taxa according to their influence on the most parsimonious topology.

Usage

```
TaxonInfluence(
  dataset,
  tree = NULL,
  Distance = ClusteringInfoDistance,
  calcWeighted = TRUE,
  savePath = NULL,
  useCache = FALSE,
  verbosity = 3L,
  ...
)
```

Arguments

dataset	A phylogenetic data matrix of phangorn class <code>phyDat</code> , whose names correspond to the labels of any accompanying tree. Perhaps load into R using ReadAsPhyDat . Additive (ordered) characters can be handled using Decompose .
tree	Optimal tree or summary tree (of class "phylo") or list of trees (of class "list" or "multiPhylo") against which results should be evaluated. If NULL, an optimal tree will be sought using parsimony search with the parameters provided in
Distance	Function to calculate tree distance; default: ClusteringInfoDistance() .
calcWeighted	Logical specifying whether to compute the distance-weighted mean value.

savePath	Character giving prefix of path to which reduced trees will be saved (with <code>write.nexus()</code>). File names will follow the pattern <code>paste0(savePath, droppedTaxonName, ".nex")</code> ; savePath should thus contain a trailing / if writing to a directory, which will be created if it does not exist. Special characters will be removed from leaf labels when creating the file path (using <code>path_sanitize()</code>). If NULL, computed trees will not be saved.
useCache	Logical vector; if TRUE, previous tree search results will be loaded from the location given by savePath, instead of running a fresh search with the specified dataset and parameters.
verbosity, ...	Parameters for <code>MaximizeParsimony()</code> . Tree search will be conducted using tree as a starting tree.

Details

`TaxonInfluence()` follows the approach of Mariadassou et al. (2012) in repeating tree search whilst leaving each taxon in turn out of the analysis, and measuring the distance of reconstructed trees from the optimal tree obtained when all taxa are included in phylogenetic inference.

As Denton and Goolsby (2018) emphasize, the Robinson–Foulds distance is unsuitable for this purpose; this function allows the user to specify a preferred tree distance measure, defaulting to the clustering information distance (Smith 2020). Because optimal parsimony trees are not equiprobable, taxon influence is ranked based on the maximum and minimum tree-to-tree distances between optimal trees.

Value

`TaxonInfluence()` returns a matrix listing the phylogenetic influence of each taxon, measured in the units of the chosen tree distance metric (default = bits). Columns denote taxa; rows denote the maximum, distance-weighted mean, and minimum distance between optimal tree sets.

Distance-weighted mean

Sets of equally parsimonious trees are not statistical samples of tree space, but are biased towards areas of uncertainty. It is possible that a set of trees contains all possible resolutions of a particular clade, and a single other topology in which that clade does not exist – essentially two distinct solutions, one (*a*) which could be summarised with a summary tree that contains a polytomy, and another (*b*) which could be summarized by a perfectly resolved tree. Neither of these scenarios is preferable under the principles of parsimony; but summary statistics (e.g. mean, median) will be strongly influenced by the many trees in group *a*, thus underplaying the existence of solution *b*.

`TaxonInfluence()` uses an *ad hoc* method to produce summary statistics after weighting for trees' distance from other trees. Trees that have few close neighbours contribute more to the weighted mean, thus reducing the influence of many trees that differ only in small details. This distance-weighted mean is thus less prone to bias than a simple mean – it is no more statistically valid, but (potentially) provides a more representative summary of comparisons between sets of trees.

TBR *Tree bisection and reconnection (TBR)*

Description

TBR performs a single random TBR iteration.

Usage

```
TBR(tree, edgeToBreak = NULL, mergeEdges = NULL)

TBRMoves(tree, edgeToBreak = integer(0))

## S3 method for class 'phylo'
TBRMoves(tree, edgeToBreak = integer(0))

## S3 method for class 'matrix'
TBRMoves(tree, edgeToBreak = integer(0))

TBRSwap(
  parent,
  child,
  nEdge = length(parent),
  edgeToBreak = NULL,
  mergeEdges = NULL
)

RootedTBR(tree, edgeToBreak = NULL, mergeEdges = NULL)

RootedTBRSwap(
  parent,
  child,
  nEdge = length(parent),
  edgeToBreak = NULL,
  mergeEdges = NULL
)
```

Arguments

tree	A bifurcating tree of class phylo , with all nodes resolved;
edgeToBreak	(optional) integer specifying the index of an edge to bisect/prune, generated randomly if not specified. Alternatively, set to -1 to return a complete list of all trees one step from the input tree.
mergeEdges	(optional) vector of length 1 or 2, listing edge(s) to be joined: In SPR, this is where the pruned subtree will be reconnected. In TBR, these edges will be reconnected (so must be on opposite sides of edgeToBreak); if only a single edge is specified, the second will be chosen at random

parent	Integer vector corresponding to the first column of the edge matrix of a tree of class <code>phylo</code> , i.e. <code>tree[["edge"]][, 1]</code>
child	Integer vector corresponding to the second column of the edge matrix of a tree of class <code>phylo</code> , i.e. <code>tree[["edge"]][, 2]</code> .
nEdge	(optional) Number of edges.

Details

Branch lengths are not (yet) supported.

All nodes in a tree must be bifurcating; `ape::collapse.singles` and `ape::multi2di` may help.

Value

`TBR()` returns a tree in `phyDat` format that has undergone one TBR iteration.

`TBRMoves()` returns a `multiPhylo` object listing all trees one TBR move away from `tree`, with edges and nodes in preorder, rooted on the first-labelled tip.

`TBRSwap()` returns a list containing two elements corresponding to the rearranged parent and child parameters.

Functions

- `TBRSwap()`: faster version that takes and returns parent and child parameters
- `RootedTBR()`: Perform TBR rearrangement, retaining position of root
- `RootedTBRSwap()`: faster version that takes and returns parent and child parameters

Author(s)

Martin R. Smith (martin.smith@durham.ac.uk)

References

The TBR algorithm is summarized in Felsenstein J (2004). *Inferring phylogenies*. Sinauer Associates, Sunderland, Massachusetts.

See Also

`RootedTBR()`: useful when the position of the root node should be retained.

Other tree rearrangement functions: `NNI()`, `SPR()`

Examples

```
library("ape")
tree <- rtree(20, br=NULL)
TBR(tree)
```

UnloadMorphy	<i>Destroy a Morphy object</i>
--------------	--------------------------------

Description

Destroys a previously-created Morphy object.

Usage

```
UnloadMorphy(morphObj)
```

Arguments

morphObj Object of class morphy, perhaps created with [PhyDat2Morphy\(\)](#).

Details

Best practice is to call `morphObj <- UnloadMorphy(morphObj)` Failure to do so will cause a crash if `UnloadMorphy()` is called on an object that has already been destroyed

Value

Morphy error code, decipherable using [mpl_translate_error](#)

Author(s)

Martin R. Smith

WhenFirstHit*When was a tree topology first hit?*

Description

Reports when each tree in a list was first found by tree search. This information is read from the `firstHit` attribute if present. If not, trees are taken to be listed in the order in which they were found, and named according to the search iteration in which they were first hit - the situation when trees found by `MaximizeParsimony()` are saved to file.

Usage

```
WhenFirstHit(trees)
```

Arguments

`trees` A list of trees, or a `multiPhylo` object.

Value

`trees`, with a `firstHit` attribute listing the number of trees hit for the first time in each search iteration.

Author(s)

[Martin R. Smith \(martin.smith@durham.ac.uk\)](mailto:martin.smith@durham.ac.uk)
